# Back to YR studies

No PID detectors  
No support/service material

From my presentation for YR-Calorimetry, Jun 30, 2020

## What hits the EMCal

After  $\sim 4.5\%$  of  $X_0$

Single 10 GeV/c electrons generated

5

Original electron reaches EMCal with part of its energy radiated

Long and flat tail towards lower energy

A lot of soft particles, mainly photons

# Making setup simpler

1 GeV/c electron

Number of particles hitting the EMCal (>20 MeV)

~40% of events with >1 particle hitting the EMCal (>20 MeV)

Number of clusters in the EMCal (>20 MeV)

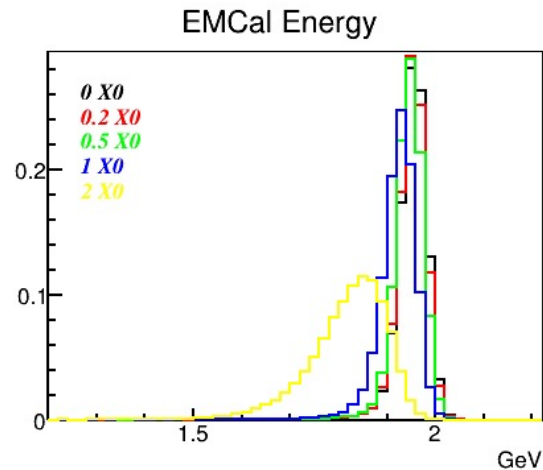

¼ of events with >1 cluster (> 20 MeV)

# Making setup simpler

2 GeV/c electron

Energy is not lost for the thickness  $< 0.5 X_0$   
(Consistent with EM shower long. profile)

But energy gets redistributed in the EMCal  
(Electron + radiated  $\gamma$  and  $e^+e^-$ )

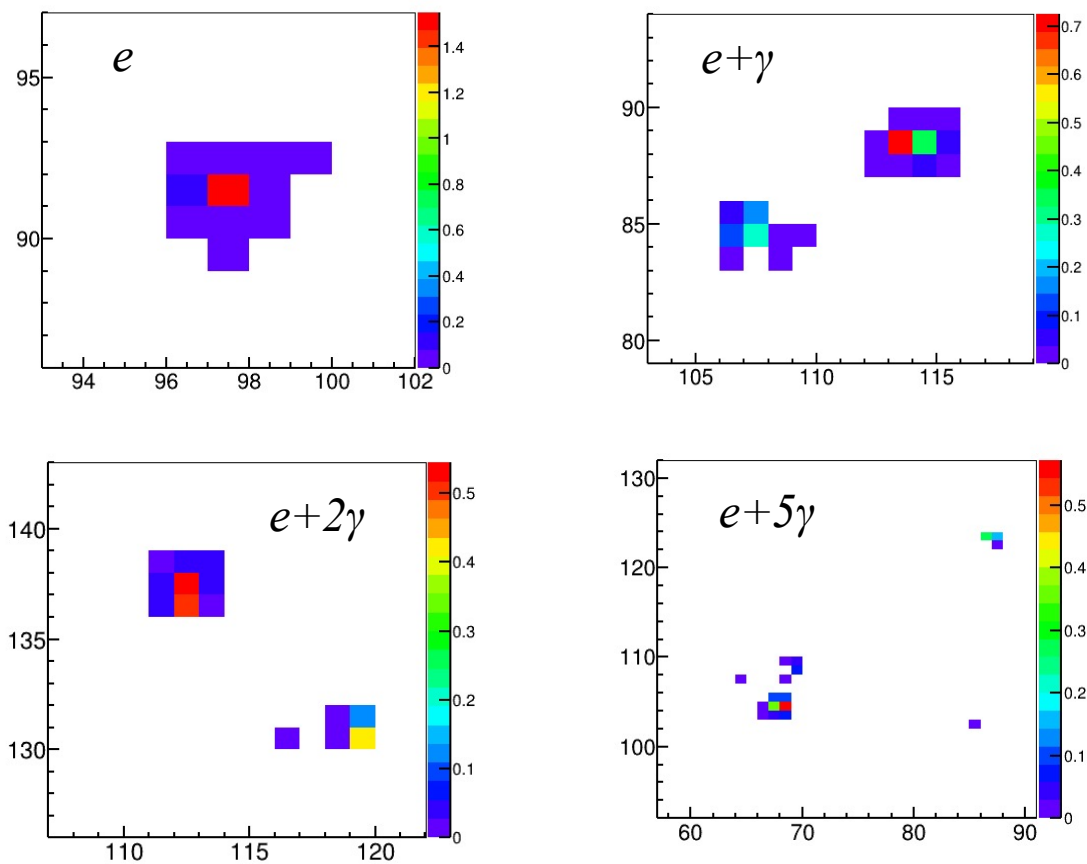

For the material of  $< 0.5 X_0$ , no energy is missing

The key question is how well we can reconstruct/associate the energy related to original electron

# eReco in EMCal with material on the way

Single 2 GeV electrons simulation  
with  $\sim 5\%$  material on the way to EMCal

Energy in EMCal towers

# Quantifying the effect

From my presentation for YR-Calorimetry, Jun 30, 2020

## “Efficiency” of $e$ reco

$$E_{EMC} > E_{nom} - 2 \sigma_{EMC}$$

How electron is “modified” as seen by the EMCal

Losses vs  $p$  (GeV/c)

Expected to be 2.3% for a pure gaussian response

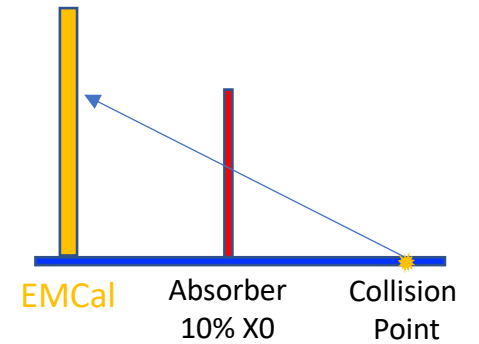

Huge effect from  $\eta = -3$  to  $\eta = -2$

8

Now, do the same in the following

# Associated cluster vs energy sum

Eff loss vs p

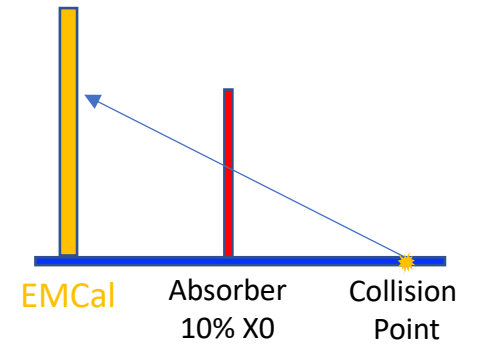

Single (track associated) cluster doesn't represent well the electron energy, particularly at low momenta

Need to combine electron cluster with accompanying radiation (including very low energy one)

# Energy sum: cluster threshold effect

A lot of low energy radiated photons  
=> sensitivity to energy threshold

Eff loss vs p

Minor effect at  $p > 5$  GeV/c  
Sharply increasing effect at  $p < 2$  GeV/c

Need to measure photons to as low energy as possible (down to 20-50 MeV)

# Radiated photons are not everywhere

From my presentation for YR-Calorimetry, Jul 14, 2020

No PID detectors  
No support/service material

## Radiated photon topology

Radiated photon relative electron position at the EMCal

Radiated photons are distributed relative to a parent electron:  
Nearly at the same  $\eta$   
At negative  $\phi$

4

May not be able to sum up the cluster energy in the whole EMCal (will pick up not related energy)

But we may not need to: the radiated photons are distributed in arcs at pseudorapidity of the parent electron

# Radiated Photon Topology Cut

Eff loss vs p

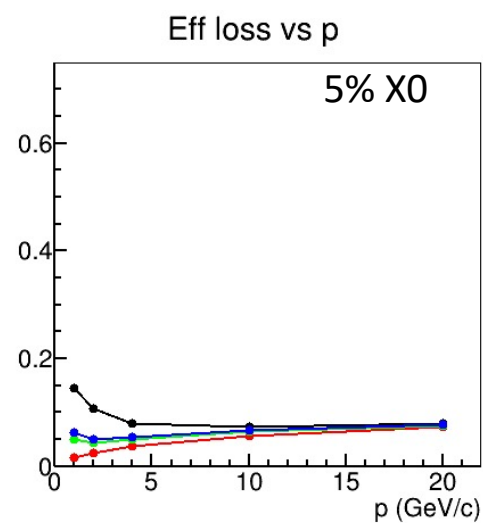

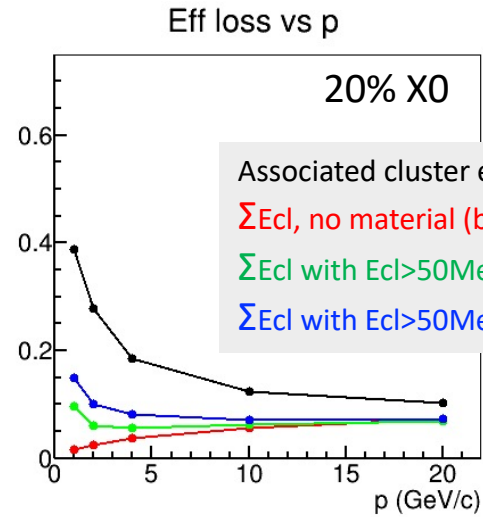

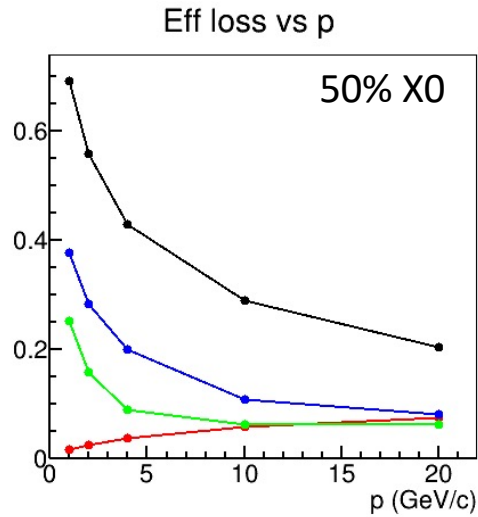

Just a very simple cut:

$\Delta\eta=\pm 0.2$  window leads to small enough  
eff loss

$\Delta\phi=\pm 0.5$  doesn't introduce any losses

Smarter technique for radiated photon  
ID may provide better performance

# Vs converter thickness

Associated cluster energy

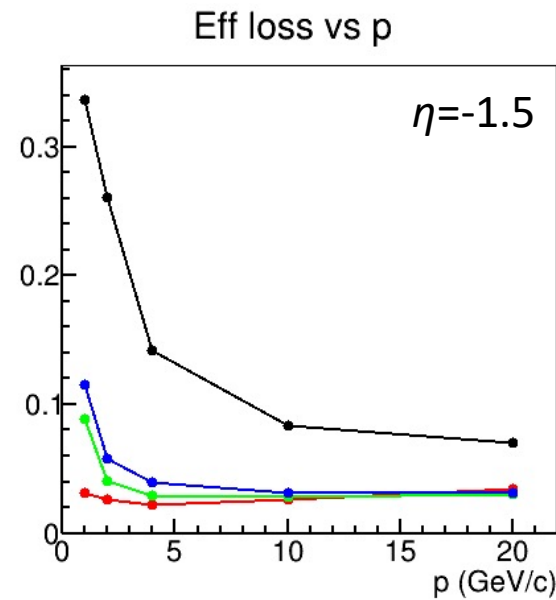

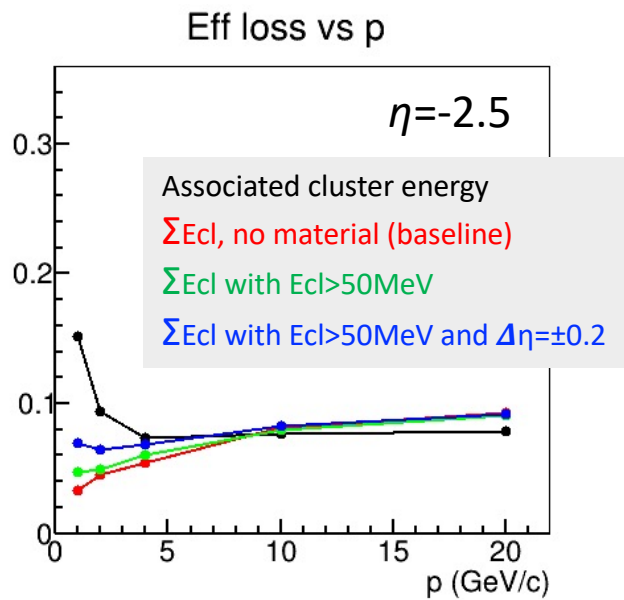

- $\Sigma E_{cl}$ , no material (baseline)
- $\Sigma E_{cl}$  with  $E_{cl} > 50 \text{ MeV}$
- $\Sigma E_{cl}$  with  $E_{cl} > 50 \text{ MeV}$  and  $\Delta\eta = \pm 0.2$

Electron reco from associated cluster leads to sizable eff loss even for 5%X0 absorber

Summing up the energy in the vicinity of the electron rapidity ( $\Delta\eta = \pm 0.2$ ) recover the eff well up to 10%X0 thickness

# Vs rapidity (Bdl)

$\eta = 1.5$  vs 2.5:

A factor of 3 larger Bdl  
 ~10% larger material  
 thickness

Larger eff loss for larger Bdl

# Vs location

Closer to EMCal –  
smaller the eff loss

# Vs magnetic field

All my previous plots are for 1.5T solenoid

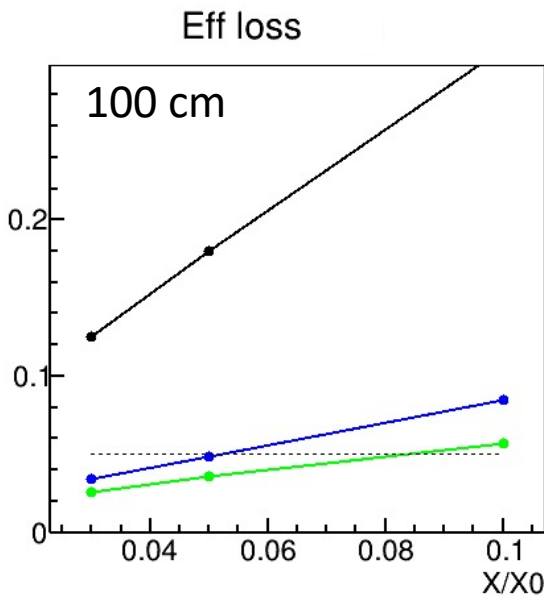

Larger eff loss for larger Bdl

# $\eta = -1.5$ , $p = 1$ GeV, $B = 1.5$ T

**The worst case:** Highest Bdl, lowest e momentum

Baseline (for no-material) subtracted

For 5% eff loss,  $B = 1.5$  T:

5-8%  $X_0$

~25%  $X_0$

~50%  $X_0$

# $\eta = -1.5$ , $p = 1$ GeV, $B = 3$ T

**The worst case:** Highest Bdl, lowest e momentum

Baseline (for no-material) subtracted

For 5% eff loss,  $B = 3$  T:

3-6%  $X_0$

~20%  $X_0$

~50%  $X_0$

# Low energy photons

Low energy photon measurements (down to 100 MeV?) may impose tougher requirements:

High probability for a converted photon to be lost (too low energy e+e- to reliably track)

7%X0 => 5% photons converted (lost?)

Low energy (shallow) shower => more energy absorbed on the way

May require <30%X0  
in front of EMCal  
(because of energy loss in it)

# Summary for PWO-like EMCal in e-endcap

- Electron reco from associated cluster leads to sizable eff loss even for 5%X0 absorber
  - ⇒ Need to include clusters from radiated photons
- EMCal should be capable to measure radiated photons down to at least 50 MeV (or, better, down to 20 MeV)
  - ⇒ The level of noise should be minimized
- Effect of material after electron reco:
  - Larger for larger Bdl
  - Increases from high to low p
  - ~5%X0 acceptable within 100 cm from the vertex
  - ~20%X0 acceptable if at ~150cm (within 50cm from EMCal)
  - Minimized if just in front of EMCal (up to 50%X0 is tolerable)
  - Low energy photon measurement requirements may be tougher:
    - <10%X0 on the way and <30%X0 just in front (within 10cm) of EMCal
- For lower resolution EMCal, the material limitations are relaxed
- More developed techniques for e-reco (plus rad. photons) and considering other backgrounds may modify the conclusions in some way

These limitations are exclusive

# Decay $\gamma$ from PYTHIA

Fraction of events with decay photons  
in the vicinity of DIS electron:

$$\Delta\eta = \pm 0.2$$

$$\Delta\varphi = \pm 0.5$$

The contribution of decay photons within  
topology cut (used for radiated photons)  
may be kept at low enough level

The other backgrounds need to be  
evaluated too (e.g. synchrotron rad.)

# 2sigma vs 3sigma

100cm

150cm

Eff loss

Eff loss

2sigma

No dependence for black  
 Moderate dependence for blue  
 Bigger dependence for green

3sigma

# Eta = -1.5 vs -2.5

100cm

150cm

Eta = -1.5

Eta = -2.5

# Eta=-1.5, 3T, 50&100 cm

3% X0  
is ok

5% X0  
is ok

# Eta=-1.5, 3T, 150&190 cm

150cm  
(50 cm in front of EMCal)

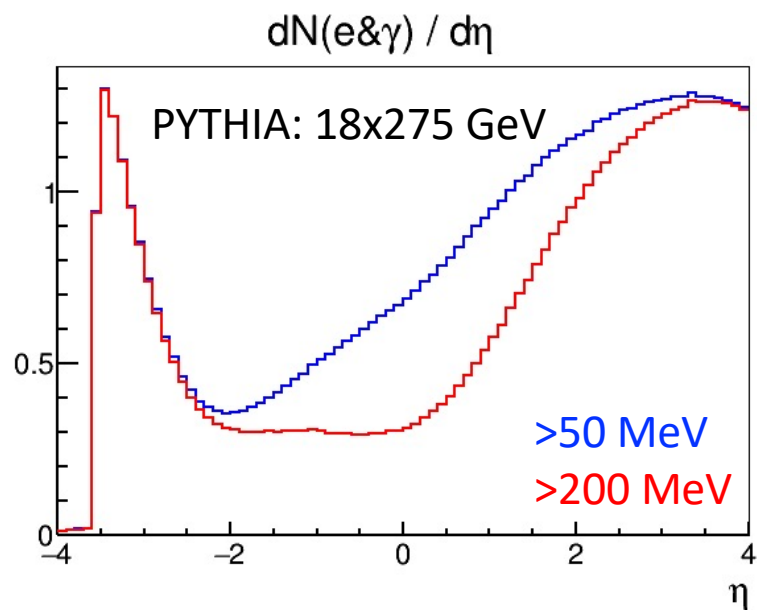

20% X0  
is ok

190cm  
(10 cm in front of EMCal)

50% X0  
is ok

# PYTHIA: e& $\gamma$ rapidity density

For  $\Delta\eta=0.2$  the probability to have a shower from e or  $\gamma$  may be >10%

# Electron radiated energy

Fraction of electrons losing:  
20% of its energy  
50% of its energy

# Photons 0.1 GeV

May require  $<30\%X_0$  in front of EMCal

May require  $<15\%X_0$  at 150cm
