July 2022

Outline

- Introduction: A Polarized Electron-Ion Collider

- I. Polarized Particle beams

- II. Proton Polarimetry

- III. Electron Polarimetry

- Conclusions

What is polarization?

Why do we need to measure it?

Core Questions of QCD

① <u>Emerging Nucleons</u>

How are gluons, sea quarks, and their intrinsic spins distributed in space and momentum in the nucleon?
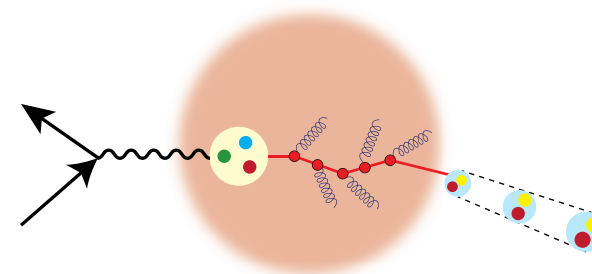

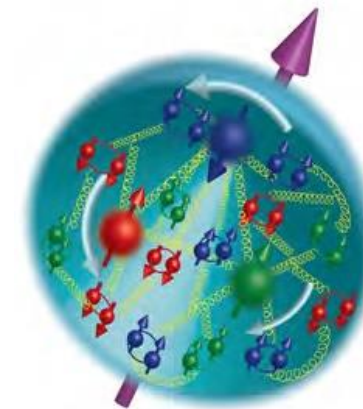

② <u>Nuclear Medium</u>

How do colored quarks and gluons and colorless jets interact with the nuclear medium?

How does the nuclear environment affect quark and gluon distributions?

③ <u>Gluon Saturation</u>

What happens to the gluon density at high energy?

Are the properties of a saturated gluonic state universal among all nuclei?

arXiv: 1212.17010

Eur. Phys. J. A52 (2016) 268
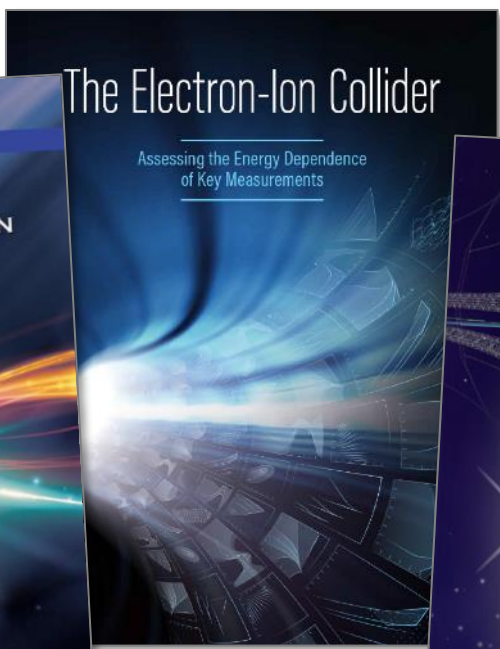

The Electron-Ion Collider
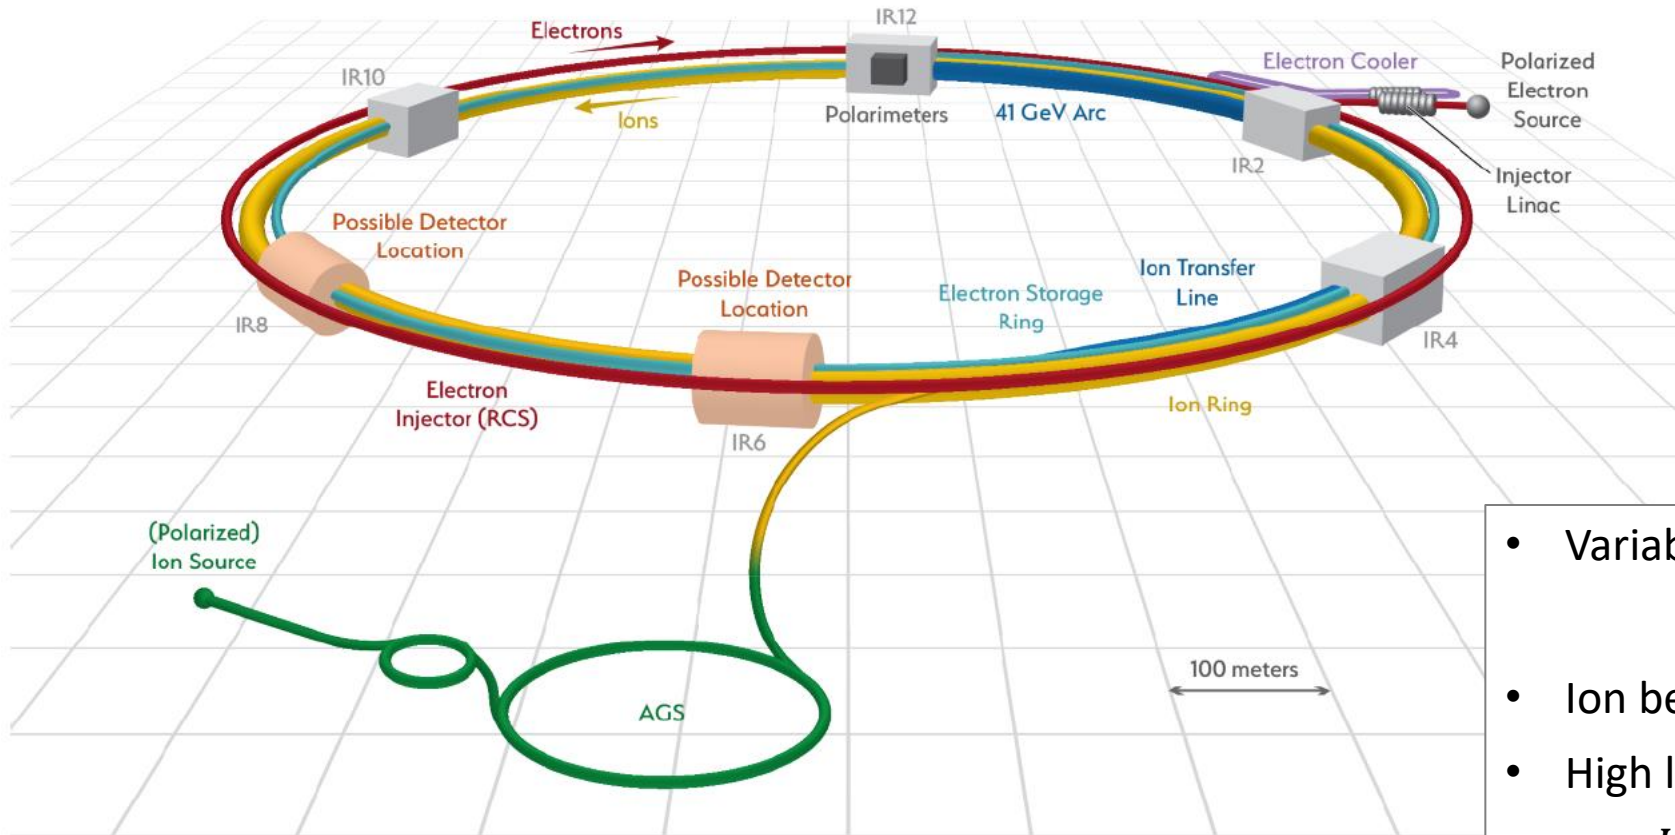

Electrons: $5 - 18$ GeV
Protons: $50 - 275$ GeV

- Variable center-of-mass energy:
$$\sqrt{s} = 20 - 140 \text{ GeV}$$
- Ion beams: protons, ^{3}He, Au, Pb, U
- High luminosity:
$$L = 10^{33} - 10^{34} \text{ cm}^{-1}\text{s}^{-1}$$
- Polarized electron and proton beams:
$$P \approx 70\%$$

What is Polarization?

Merriam-Webster

- Noun, po·lar·i·za·tion ˌpō-lə-rə-ˈzā-shən

1. the action of polarizing or state of being or becoming polarized: such as

   a. the action or process of affecting radiation and especially light so that the vibrations of the wave assume a definite form

   b. the state of radiation affected by this process

   c. an increase in the resistance of an electrolytic cell often caused by the deposition of gas on one or both electrodes

   d. MAGNETIZATION

      an instance of magnetizing or the state of being magnetized

      also: the degree to which a body is magnetized

2. division into two sharply distinct opposites

   especially: a state in which the opinions, beliefs, or interests of a group or society no longer range along a continuum but become concentrated at opposing extremes

What is Polarization?

Merriam-Webster

- Noun, po·lar·i·za·tion ˌpō-lə-rə-ˈzā-shən

1. the action of polarizing or state of being or becoming polarized: such as

    a. the action or process of affecting radiation and especially light so that the vibrations of the wave assume a definite form

    b. the state of radiation affected by this process

    c. an increase in the resistance of an electrolytic cell often caused by the deposition of gas on one or both electrodes

    d. MAGNETIZATION

       an instance of magnetizing or the state of being magnetized

       also: the degree to which a body is magnetized

2. division into two sharply distinct opposites

    especially: a state in which the opinions, beliefs, or interests of a group or society no longer range along a continuum but become concentrated at opposing extremes

Polarization is the average alignment of the magnetic moment of an ensemble of particles with respect to an external magnetic field.
For $s = \frac{1}{2}\hbar$:

$$P = \frac{n^+ - n^-}{n^+ + n^-}$$

The Figure of Merit

$$\delta\sigma = \frac{\sigma^+ - \sigma^-}{\sigma^+ + \sigma^-} \propto \delta f(x)$$

Physics observable of interest

$$\epsilon = \frac{N^+ - N^-}{N^+ + N^-}$$

If the measurement is fully polarized
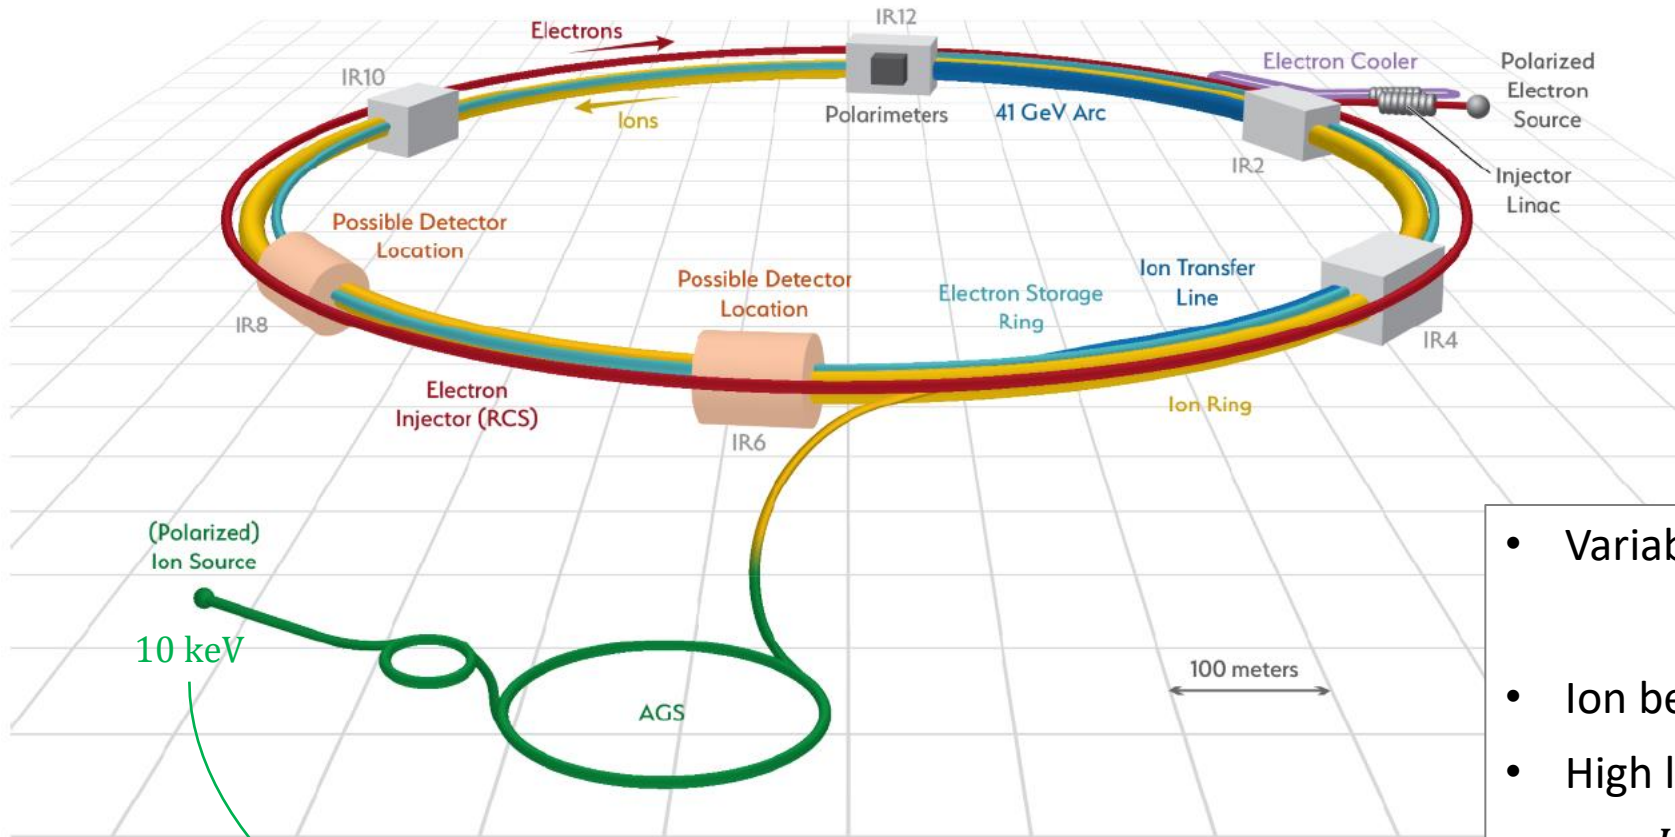

$$\epsilon = P\frac{N^+ - N^-}{N^+ + N^-}$$

With polarization $\quad P = \dfrac{n^+ - n^-}{n^+ + n^-}$

Uncertainty of physics observable $\quad \Delta_f = \Delta_E P$

Statistical uncertainty of measurement $\Delta_S = \sqrt{N}$
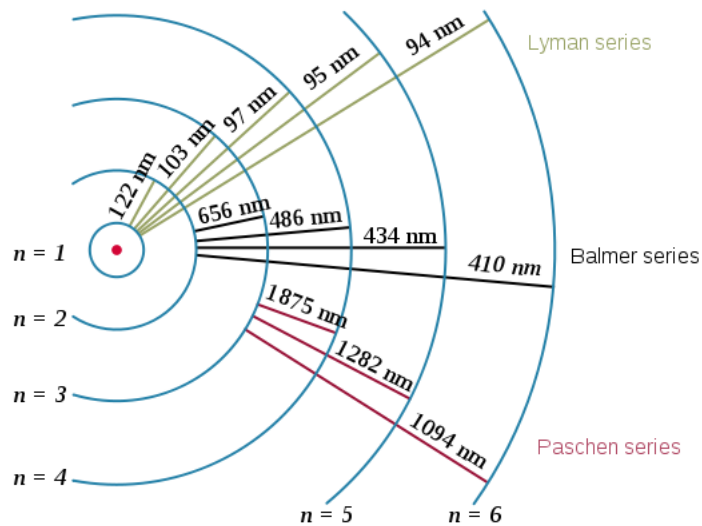

Figure of merit: $FOM = NP^2$

The Electron-Ion Collider

- Variable center-of-mass energy:
$$\sqrt{s} = 20 - 140 \text{ GeV}$$

- Ion beams: protons, ^{3}He, Au, Pb, U

- High luminosity:
$$L = 10^{33} - 10^{34} \text{ cm}^{-1}\text{s}^{-1}$$

- Polarized electron and proton beams:
$$P \approx 70\%$$

Electrons: $5 - 18$ GeV
Protons: $50 - 275$ GeV

Polarized High Energy Particle Beams
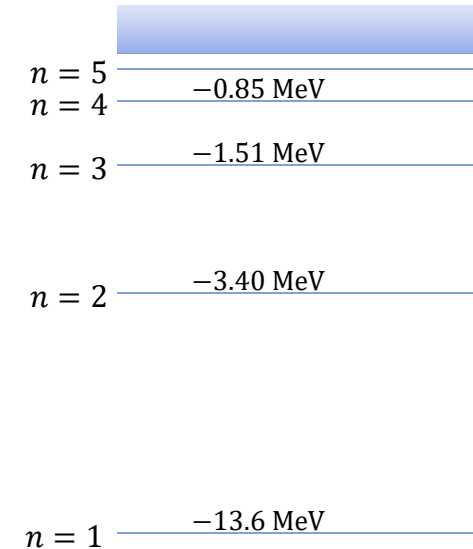

The Bohr Model of Hydrogen Atoms

The spectral lines of atomic hydrogen can be explained by the Rydberg formula:
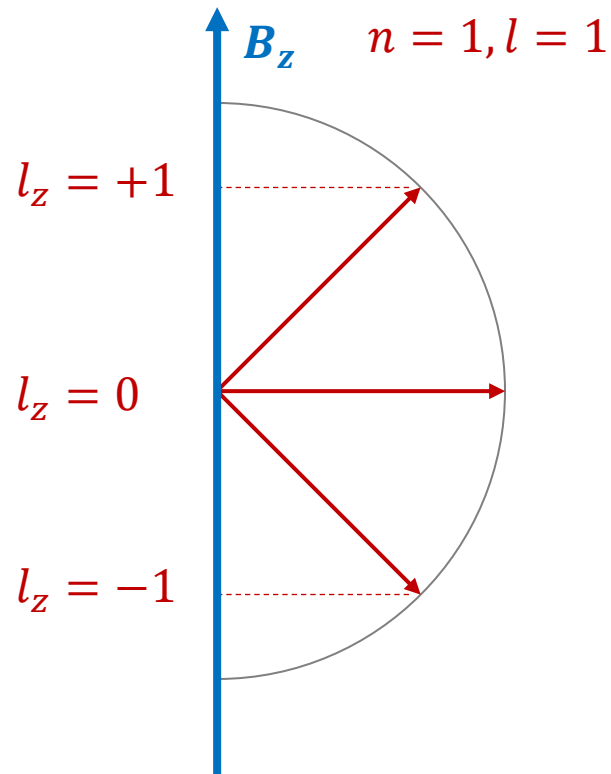

$$\frac{1}{\lambda} = R_M \left(\frac{1}{n'^2} - \frac{1}{n^2} \right)$$

$$R_\infty = \frac{m_e e^4}{8\epsilon_0^2 h^3 c} = 10\,973\,731.568\,160(21) m^{-1}$$

$$R_M = R_\infty / (1 + \frac{m_e}{M})$$

$n = 4$ -0.85 MeV

$n = 3$ -1.51 MeV

$n = 2$ -3.40 MeV

$n = 1$ -13.6 MeV

Space Quantization

B_z $n = 1, l = 1$

$l_z = +1$

$l_z = 0$

$l_z = -1$

The spectral lines of atomic hydrogen can be explained by the Rydberg formula:

$$\frac{1}{\lambda} = R_M \left(\frac{1}{n'^2} - \frac{1}{n^2} \right)$$

An external magnetic field introduces splitting of the energy levels, $l < n$:

$$2l + 1$$

The orbital angular momentum l is related to a magnetic moment m, the energy splitting is:
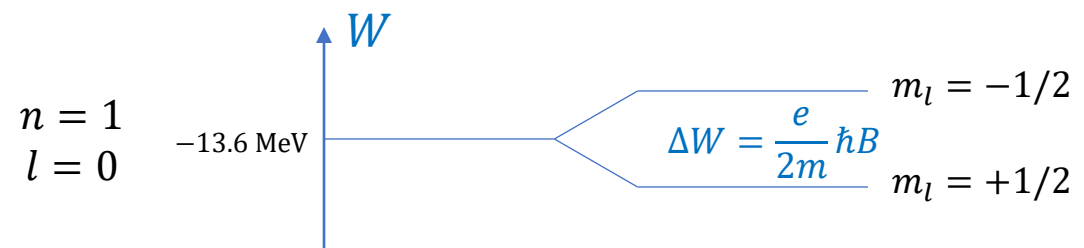

$$\Delta W = -m\mu B_z$$

$n = 5$
$n = 4$ —— -0.85 MeV

$n = 3$ —— -1.51 MeV

$n = 2$ —— -3.40 MeV

$n = 1$ —— -13.6 MeV

# Space Quantization

B_z $s = 1/2$

$s_z = +1/2$

$s_z = -1/2$

The electron has a magnetic moment which is related to an intrinsic angular momentum, $s = \frac{1}{2}\hbar$.

It introduces a fine splitting of the energy levels.
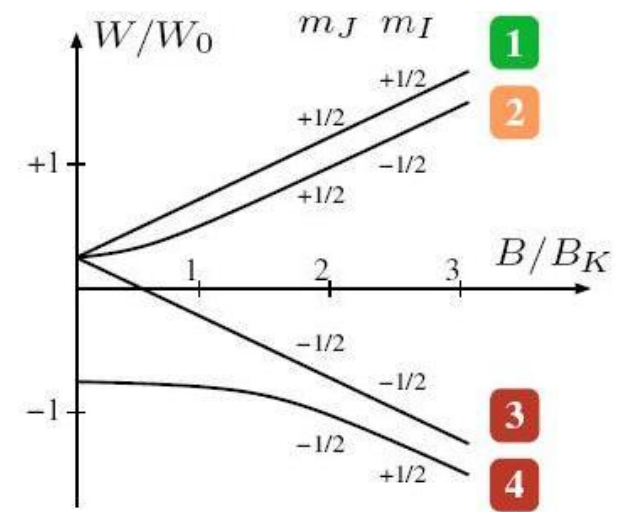

W

$n = 1$
$l = 0$

-13.6 MeV

$\Delta W = \frac{e}{2m}\hbar B$

$m_l = -1/2$

$m_l = +1/2$

Space Quantization

B_z $s = 1/2$

$s_z = +1/2$

$s_z = -1/2$

The electron has a magnetic moment which is related to an intrinsic angular momentum, $s = \frac{1}{2}\hbar$.

It introduces a fine splitting of the energy levels.

The magnetic moment of the nucleus introduces an additional hyperfine splitting.

Spin Polarized Protons

- Stern-Gerlach (1922) demonstrated that the electron spin is quantized.

Oven producing beam of silver atoms

Spin up $S_z = \frac{1}{2}\hbar$

Spin down $S_z = -\frac{1}{2}\hbar$

non-uniform magnetic field $\dfrac{dB}{dz}$

B_z

$s_z = +1/2$

$s_z = -1/2$

Spin Polarized Protons

- Stern-Gerlach (1922) demonstrated that the electron spin is quantized.

- Use a similar setup as a filter to produce polarized protons.

- The magnetic moment of the nucleus is much smaller than that of the electron.

Spin Polarized Protons

- Stern-Gerlach (1922) demonstrated that the electron spin is quantized.

- Use a similar setup as a filter to produce polarized protons.

- The magnetic moment of the nucleus is much smaller than that of the electron.

- There is a limit to the polarization (temperature, magnetic field, power of rf unit).

- We need to keep the particles on a circle.

- There is a closed orbit.

- Beam has a size and momentum spread.

- Particles oscillate around the closed orbit (betatron oscillation).

- Periodicity can lead to resonances and beam instability.

- The magnetic moment of particles precesses in magnetic fields.

$$\frac{d\vec{S}}{dt} = -\left(\frac{e}{\gamma m}\right)\left[G\gamma\vec{B}_\perp + (1+G)\vec{B}_\parallel\right] \times \vec{S}$$

$$\frac{d\vec{v}}{dt} = -\left(\frac{e}{\gamma m}\right)\vec{B} \times \vec{v}$$

$$G = 1.7928$$
$$\gamma = E/m$$

Depolarizing Resonances

Thomas-BMT equation:

$$\frac{d\vec{S}}{dt} = -\left(\frac{e}{\gamma m}\right)\left[G\gamma\vec{B}_\perp + (1+G)\vec{B}_\parallel\right] \times \vec{S}$$

$$\frac{d\vec{v}}{dt} = -\left(\frac{e}{\gamma m}\right)\vec{B} \times \vec{v}$$

$$G = 1.7928$$
$$\gamma = E/m$$

L.H. Thomas "The kinematics of an electron with an axis." *The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science* 3.13 (1927)

V. Bargmann, L. Michel, and V.L. Telegdi "Precession of the polarization of particles moving in a homogeneous electromagnetic field." *Physical Review Letters* 2.10 (1959)

- The spin tune Q_s is the number of precessions per revolution.
- There are two types of depolarizing resonances
    - Intrinsic resonances
    $$\gamma G = kP \pm (\nu_y - 2)$$
    - Imperfection resonances
    $$\gamma G = k$$

The resonance strength depends on the local orbit distortion, magnetic field, and crossing speed.
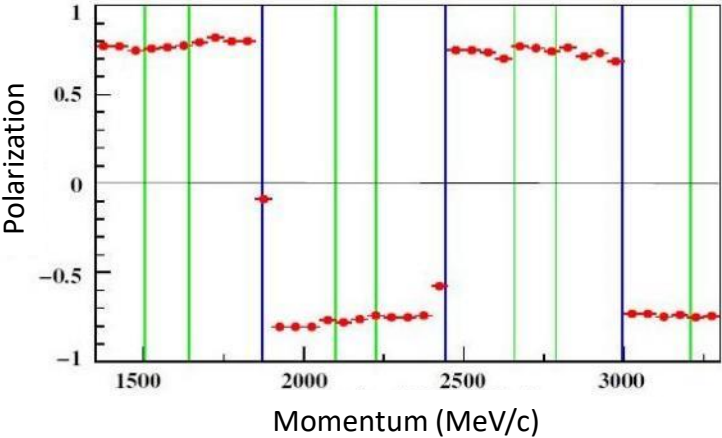

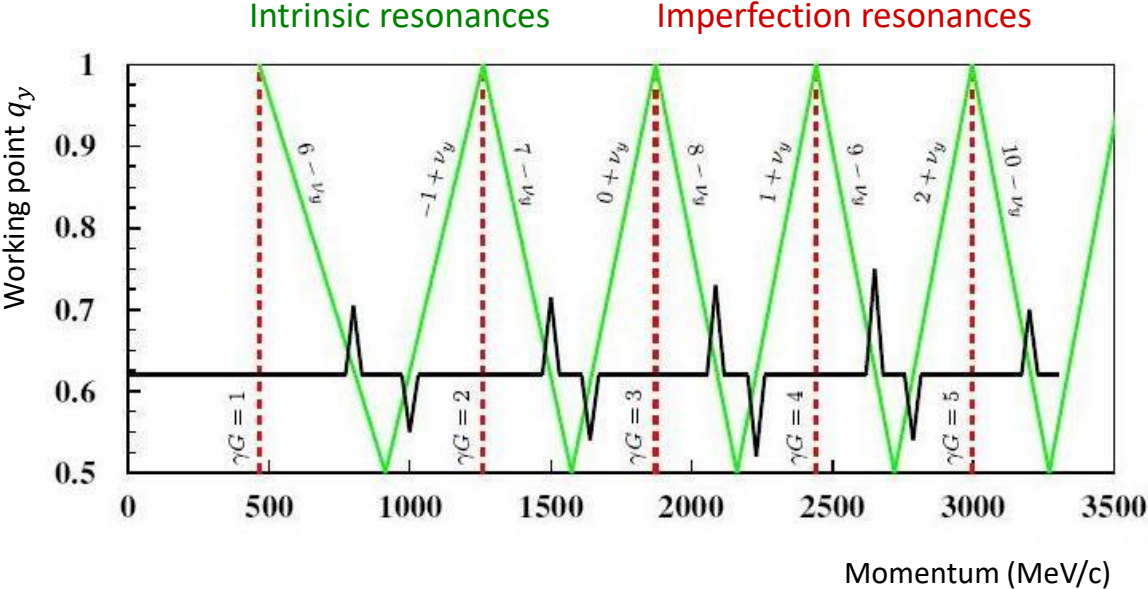

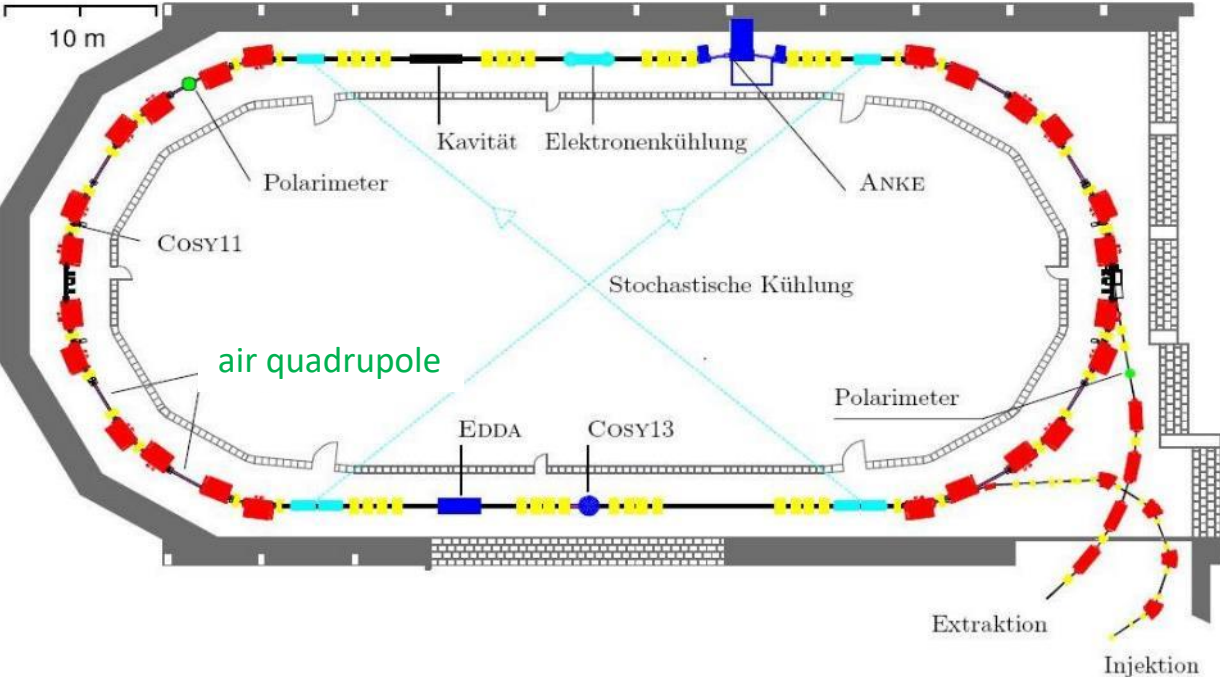

The number of resonances grows linearly with the top energy.

Example: COSY

Cooler Synchrotron at FZ Jülich, Germany

Proton accelerator / storage ring

$p_{max} = 3.3 \text{ GeV/c}$

The Relativistic Heavy Ion Collider

"Configuration Manual Polarized Proton Collider at RHIC." I. Alekseev et al. (2004)

Figure 1.1: The Brookhaven hadron facility complex, which includes the AGS Booster, the AGS, and RHIC. The RHIC spin project will install two snakes per ring with four spin rotators per detector for achieving helicity-spin experiments.

Spin Resonances in RHIC

- Imperfection resonances
  - $\nu_{spin} = \gamma G = n$
  - integer n
- Intrinsic resonances
  - $\nu_{spin} = \gamma G = kP + \nu_y$
  - integer k
  - superiodicity P
 - vertical betatron tune ν_y

Resonance Mitigation

- Deliberately advance the spin precession to avoid resonance conditions

- Group of dipole magnets with alternating horizontal and vertical field directions which rotates the spin vector by 180°

Strong AGS Snake
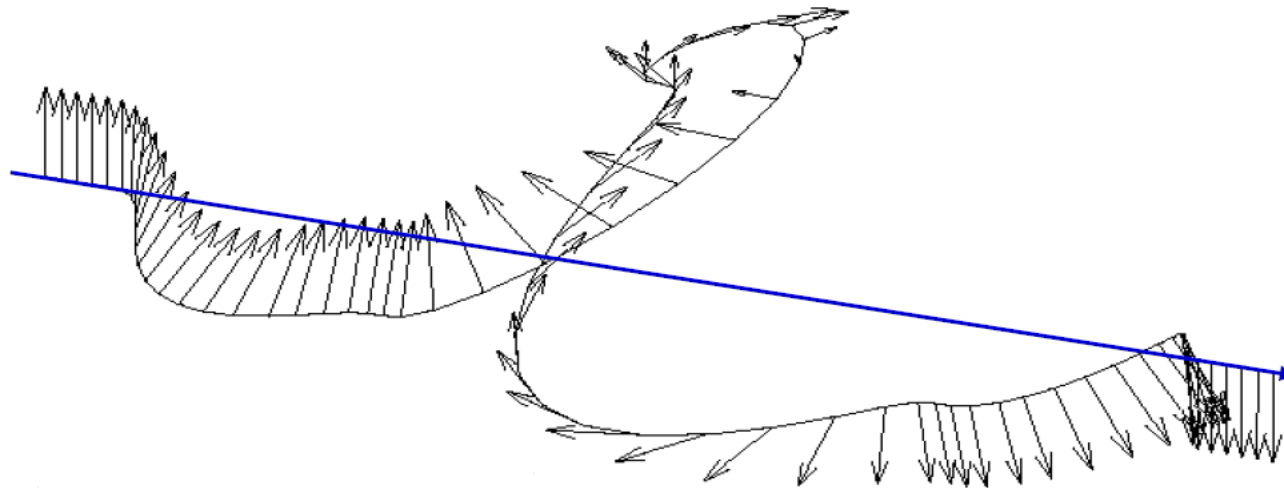

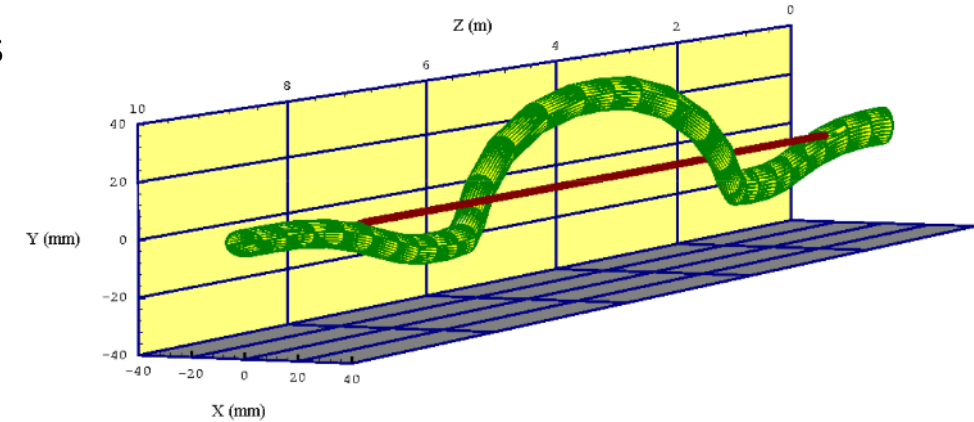

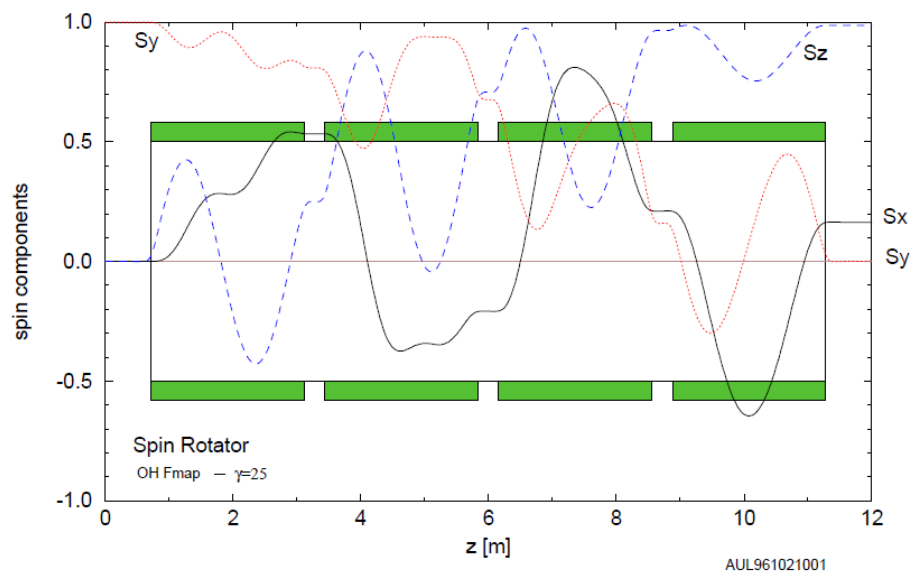

# Spin Motion through Siberian Snake
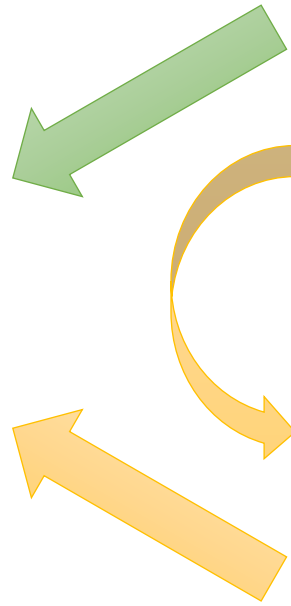

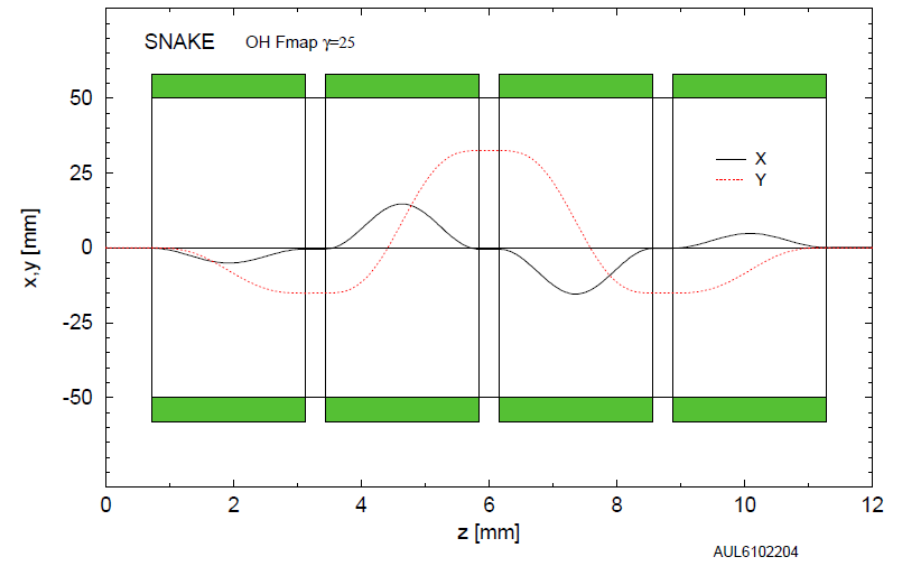

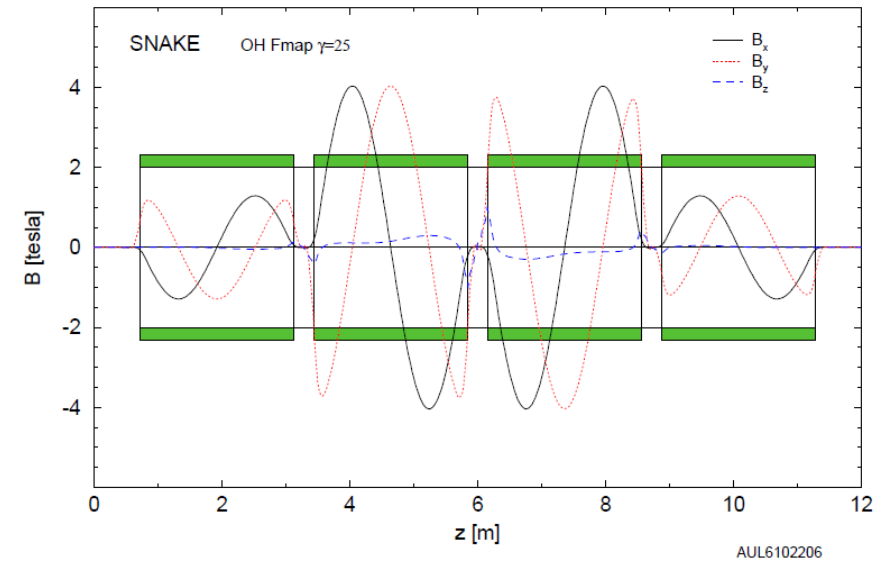

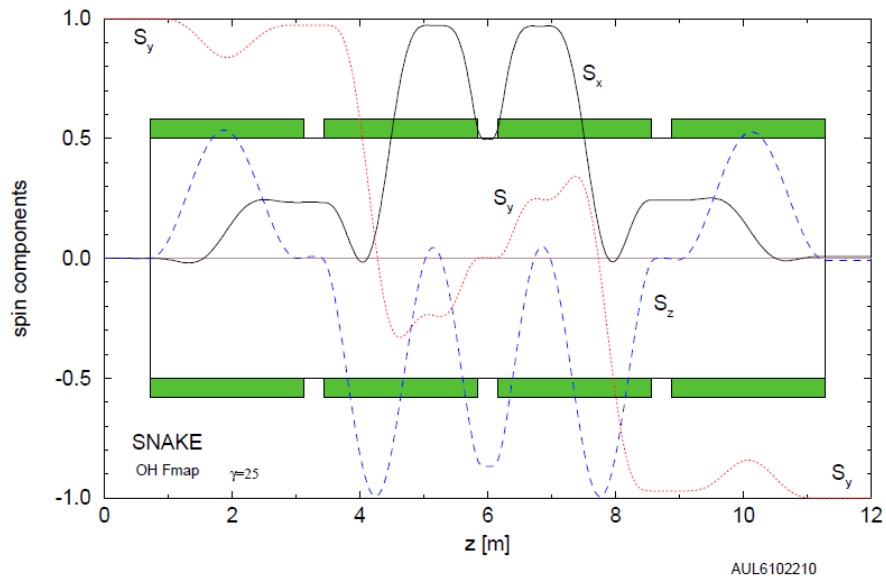

RHIC Proton Polarization

During the first 250 GeV beam operation in 2009

Spin Motion through a Spin Rotator

- The stable spin direction in a circular accelerator is vertical.
- Experiments also require longitudinal polarization.
- Spin rotators before and after each experiment.
- Transverse polarization remnant can cause systematic uncertainties in physics observables.
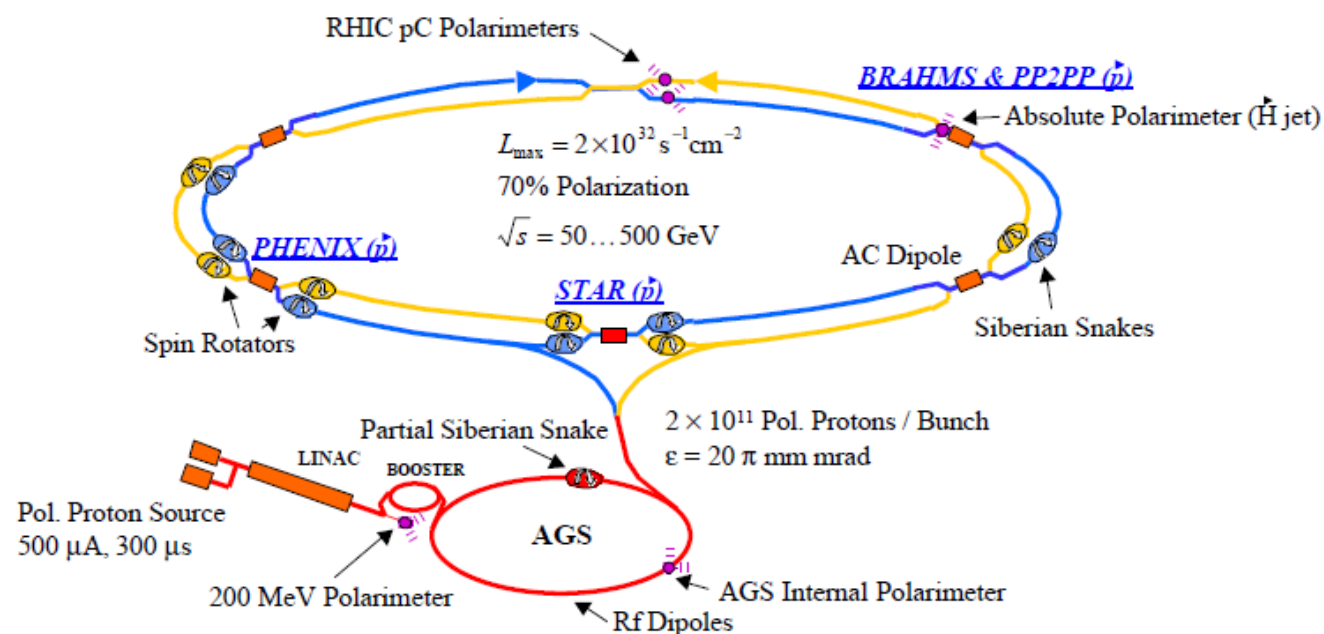

Synchrotron Radiation

- Acceleration of electrical charge emits an electromagnetic wave.
- Relativistic boost γ in the laboratory frame turns the radiation in the direction of the charged particle.
- An electron synchrotron emits a universal, continuous spectrum with single parameter ϵ_c.
- The radiated power is $P \propto E^4/\rho$

$$\gamma = \frac{1}{\sqrt{1-\left(\frac{v}{c}\right)^2}} = \frac{E}{m_0 c^2}$$
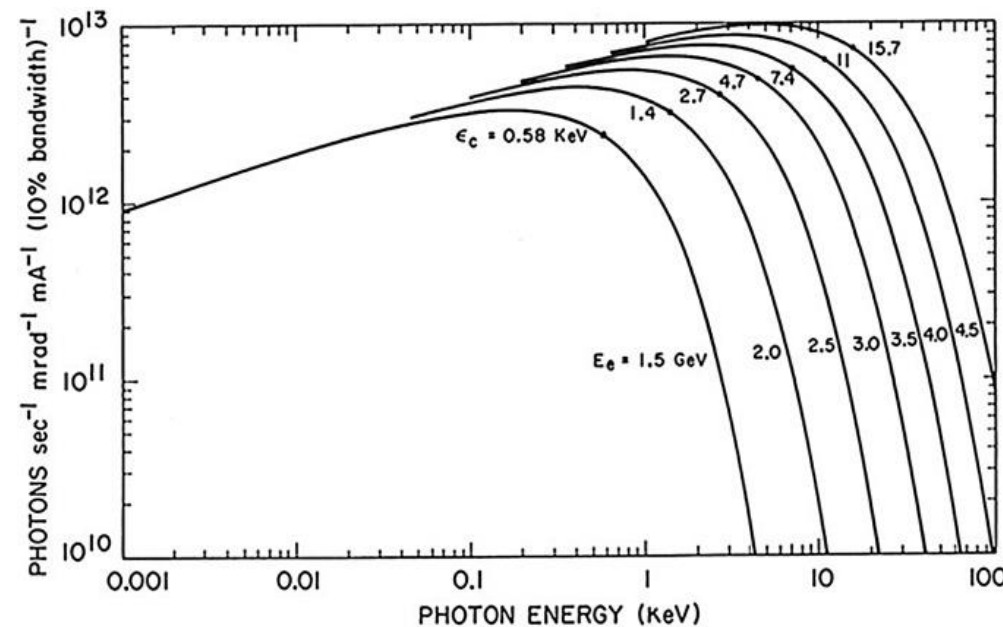

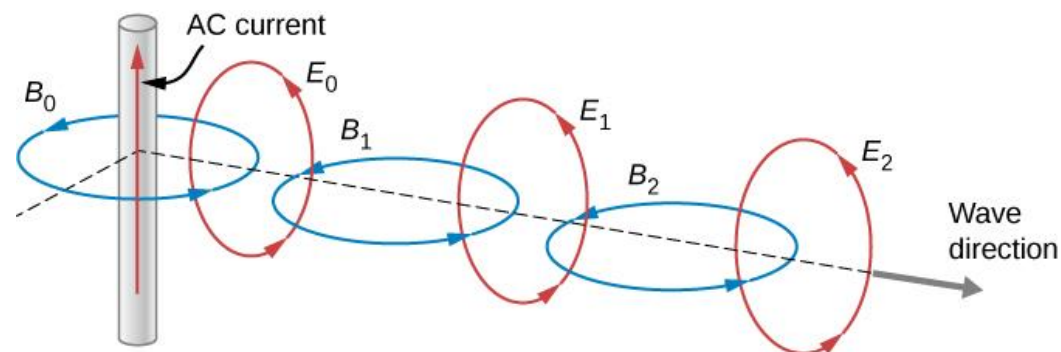

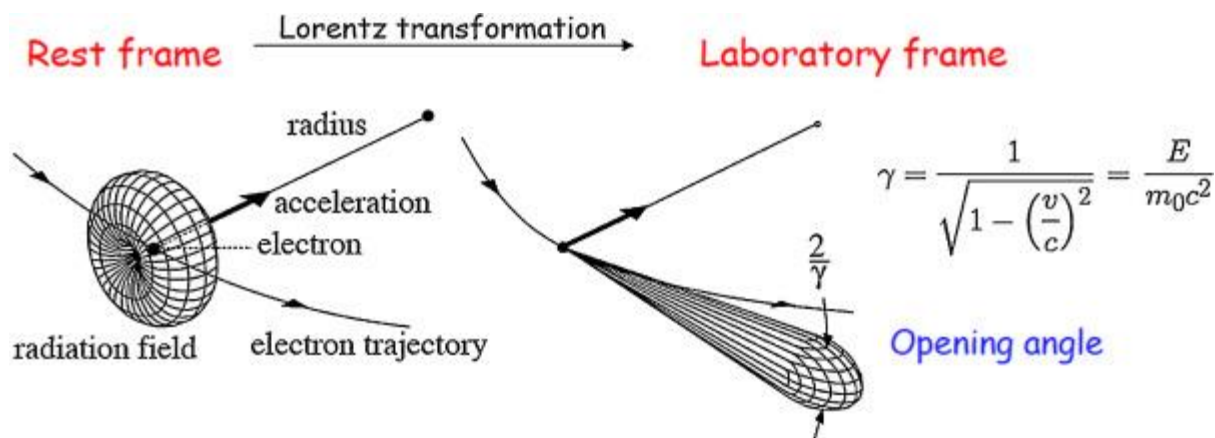

W. Eberhard "Synchrotron radiation: A continuing revolution in X-ray science" Journal of Electron Spectroscopy and Related Phenomena 200 (2015)

K. Wille "Physik der Teilchenbeschleuniger und Synchrotronstrahlungsquellen" Teubner (1996)
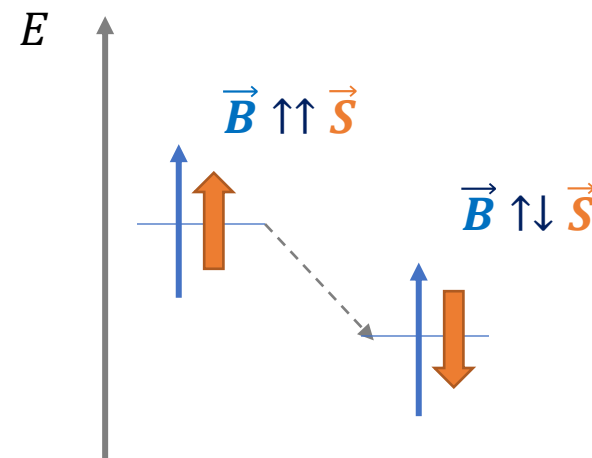

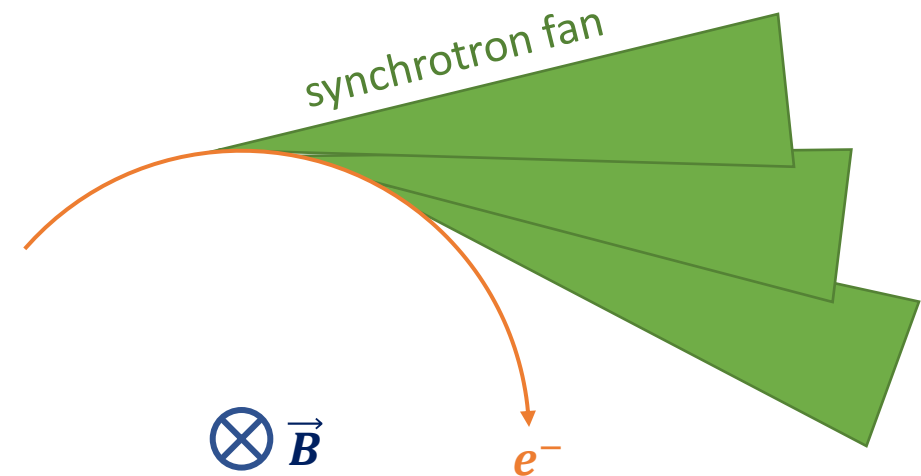

Synchrotron Radiation

- Acceleration of electrical charge emits an electromagnetic wave.

- Relativistic boost γ in the laboratory frame turns the radiation in the direction of the charged particle.

- An electron synchrotron emits a universal, continuous spectrum with single parameter ϵ_c.

- The radiated power is $P \propto E^4/\rho$

- The emitted synchrotron radiation is polarized (electrical field in the direction of the accelerator plane).

- Synchrotron radiation leads to a polarization of the electron beam (Sokolov-Ternov effect).

$$\xi(t) = A(1 - e^{-t/\tau})$$

$$\tau = A\frac{4\pi\epsilon_0\hbar^2}{mce^2}\left(\frac{mc^2}{E}\right)^2\left(\frac{B_c}{B}\right)^3$$

Polarization limit $A = 92.4\%$

Recap: Requirements for Polarimetry

- Electron beam polarization has to be measured between $5 - 18$ GeV.

- Proton beam polarization has to be measured between $50 - 275$ GeV.

- Each store may be 8 hours long. Possibly shorter?

- The beams are bunched and will have alternating polarization states to reduce time-dependent systematic uncertainties.

- Bunch spacing is around 10 ns (about 1300 bunches in each ring).
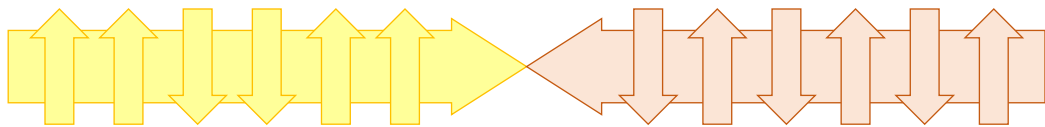

Recap: Requirements for Polarimetry
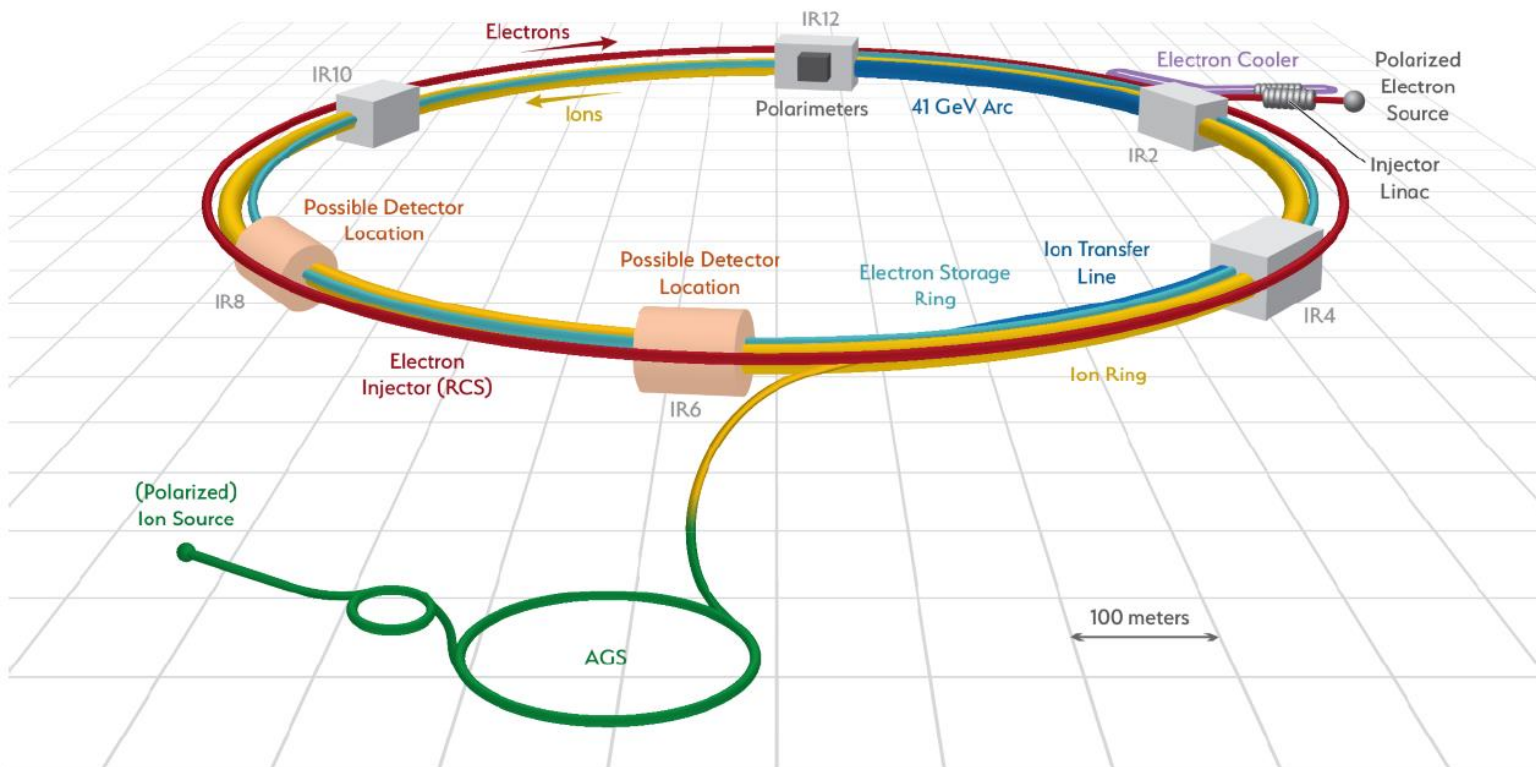

- Electron beam energies: $5 - 18$ GeV.
- Proton beam energies: $50 - 275$ GeV.
- Measure:
  - Absolute beam polarization $\Delta P / P \approx 1\%$
  - Time-dependence (polarization decay)
  - Bunch-by-bunch polarization
  - Polarization profile of bunches
  - Polarization during ramp (acceleration)
  - Polarization vector at experiment
