# Outline

- Introduction: A Polarized Electron-Ion Collider
- I. Polarized Particle beams
- **II. Proton Polarimetry**
- III. Electron Polarimetry
- Conclusions

# **Polarimetry of High Energy Hadron Beams**

# Bunch Polarization

A bunch of particles in vacuum travelling at almost the speed of light

Goes in circles, will be back in about 13  $\mu\text{s}$  (78 kHz).

It doesn't look that bad...

$$P = \frac{12 - 4}{12 + 4} = 50\%$$

# An experiment in and of itself

A bunch of particles in vacuum travelling at almost the speed of light

Goes in circles, will be back in about 13  $\mu\text{s}$  (78 kHz).

- For the determination of the polarization will have to devise a scattering experiment which is spin-dependent.
- We will need a representative sample of scattered particles to make conclusive statements about the polarization.
- Only a fraction of the scattering probability will depend on the spin:  $\sigma^{\uparrow\downarrow} = \sigma_0 \pm \sigma_s$
- It is convenient to introduce an asymmetry:  $\epsilon = \sigma^{\uparrow} - \sigma^{\downarrow} = 2\sigma_s$

# The right frame

- The momentum and spin direction define a coordinate system.

Longitudinal  $L$

Normal  $N$

Sideways  $S$

$$\mathbf{S} = \mathbf{N} \times \mathbf{L}$$

$$\varepsilon = A_N \cdot P = \frac{N_L - N_R}{N_L + N_R}$$

refers to the projectile

Analyzing power  $A_N$

$$\text{Polarization } P = \frac{n^\uparrow - n^\downarrow}{n^\uparrow + n^\downarrow}$$

# Bootstrapping...

- Elastic scattering obeys parity conservation and time invariance.
- The collision is symmetric (in the center-of-mass frame), recoil and ejectile are indistinguishable.

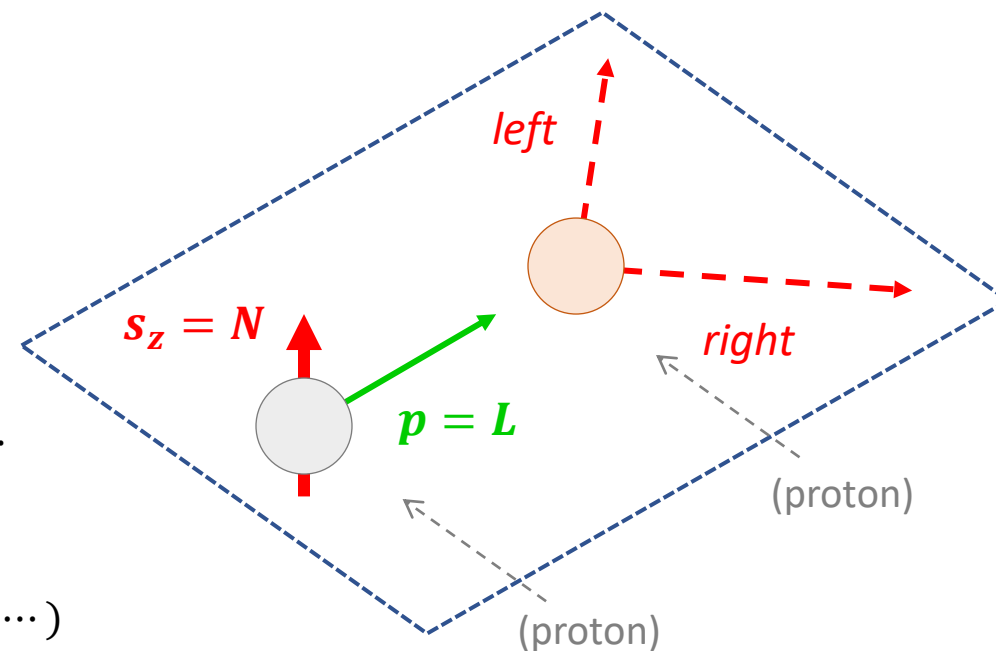

$$\rho_f = \mathbf{M} \rho_i \mathbf{M}^* \quad \rho = \sum_n p_n |n\rangle\langle n| \quad \mathbf{M} = \sum_{i,f} a_{f,i} \sigma_i \otimes \sigma_f$$

$$\rho_i = \rho_{beam} \otimes \rho_{target}$$

$$\frac{d\sigma}{d\Omega} = \text{Tr}(\rho_f) = \sum_n p_n |\langle n | \mathbf{M} | n \rangle|^2$$

$$\frac{d\sigma}{d\Omega} = a_{0000} + \sum_n P_n a_{00n0} + \sum_m Q_m a_{000m} + \sum_{m,n} P_n Q_m a_{00nm} + \dots$$

$$\frac{d\sigma}{d\Omega} = \frac{d\sigma}{d\Omega_0} \left( 1 + \sum_n P_n A_{00n0} + \sum_m Q_m A_{000m} + \sum_{m,n} P_n Q_m A_{00nm} + \dots \right)$$

→  $4^4=256$  possible Observables (25 independent parameters)

# Bootstrapping...

- Elastic scattering obeys parity conservation and time invariance.
- The collision is symmetric (in the center-of-mass frame), recoil and ejectile are indistinguishable.

$$\frac{d\sigma}{d\Omega} = \frac{d\sigma}{d\Omega_0} (1 + P_{beam}A_{00N0} + P_{target}A_{000N})$$

ejectile, recoil, projectile, target

- For elastic scattering:

$$A_{00N0} = -A_{000N}$$

$$P_{Beam} = -\frac{\epsilon_{Beam}}{\epsilon_{Target}} P_{Target}$$

# Elastic $p + p$ Scattering

- Example: EDDA @ COSY

- Kinematic correlation in elastic scattering

$$\varphi_1 - \varphi_2 = \pi$$

$$\tan \vartheta_1 \cdot \tan \vartheta_2 = 1/\gamma_{cm}^2$$

- EDDA detector
  - Scintillator hodoscope specifically designed for elastic  $p + p$  scattering

# Elastic $p + p$ Scattering

- Example: EDDA @ COSY

- Atomic hydrogen target
  - Selection of hyperfine state 1 (of 4)
  - Magnetic holding field  $B_{x,y,z} \approx 10$  G
  - Rabi unit for polarization measurement
  - Target polarization  $Q \approx 70\%$

# Elastic Scattering at RHIC energies

- The beam momentum is 100 – 250 GeV.
- A significant analyzing power exists in the Coulomb-Nuclear Interference region.

$$\varphi(s, t) = \langle \lambda_C \lambda_D | \varphi | \lambda_A \lambda_B \rangle$$

$$\begin{aligned} \varphi_1(s, t) &= \left\langle +\frac{1}{2} + \frac{1}{2} | \varphi | +\frac{1}{2} + \frac{1}{2} \right\rangle \\ \varphi_2(s, t) &= \left\langle +\frac{1}{2} + \frac{1}{2} | \varphi | -\frac{1}{2} - \frac{1}{2} \right\rangle \\ \varphi_3(s, t) &= \left\langle +\frac{1}{2} - \frac{1}{2} | \varphi | +\frac{1}{2} - \frac{1}{2} \right\rangle \\ \varphi_4(s, t) &= \left\langle +\frac{1}{2} - \frac{1}{2} | \varphi | -\frac{1}{2} + \frac{1}{2} \right\rangle \\ \varphi_5(s, t) &= \left\langle +\frac{1}{2} + \frac{1}{2} | \varphi | +\frac{1}{2} - \frac{1}{2} \right\rangle \end{aligned}$$

$$A_N \frac{ds}{dt} = -\frac{4\pi}{s^2} \text{Im} \left[ \varphi_5^{em*}(s, t) \varphi_+^{had}(s, t) + \varphi_5^{had*}(s, t) \varphi_+^{em}(s, t) \right]$$

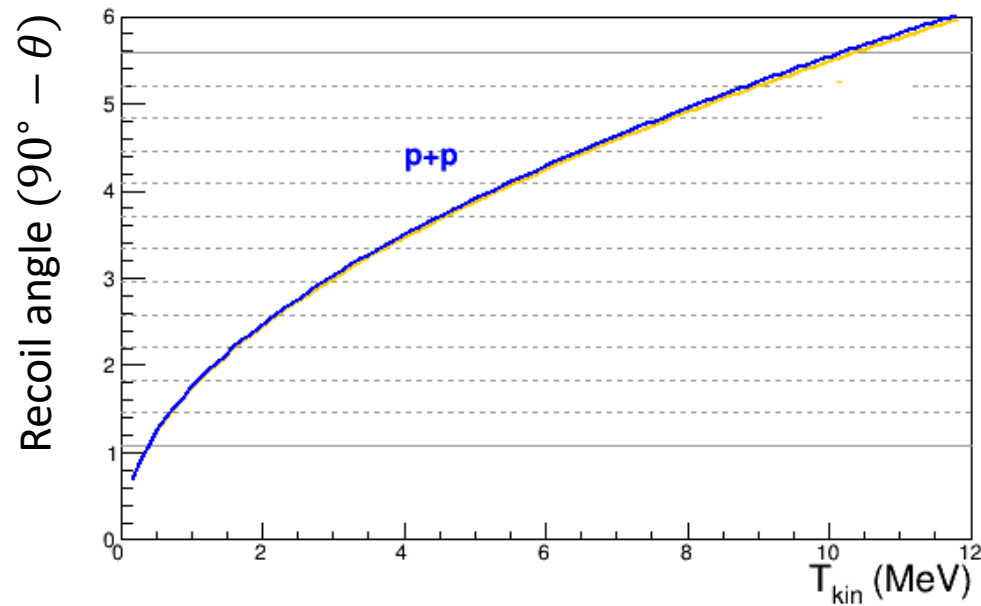

$$\text{no-flip amplitude: } \varphi_+(s, t) = \frac{1}{2} [\varphi_1(s, t) + \varphi_3(s, t)]$$

A. Poblaguev et al., Phys. Rev. D 79, 094014 (2009)

# Elastic Scattering at RHIC energies

- The beam momentum is 100 – 250 GeV.
- A significant analyzing power exists in the Coulomb-Nuclear Interference region.
- Recoil comes out almost perpendicular to the beam direction.

Kinetic energy of the recoil proton

A. Poblaguev et al., Phys. Rev. D 79, 094014 (2009)

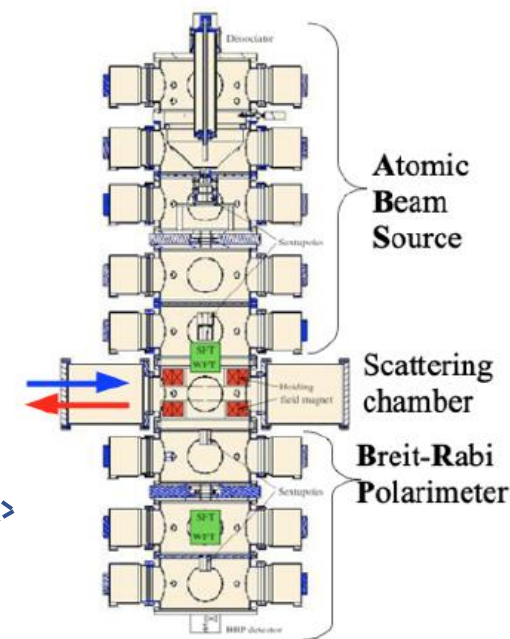

# An Absolute Polarimeter at RHIC / EIC

- Polarized atomic hydrogen jet target (HJET)

- $H_2$  source
- Dissociator
- RF unit
- Holding field
- Detectors

# An Absolute Polarimeter at RHIC / EIC

- Polarized atomic hydrogen jet target (HJET)
- Set of eight Hamamatsu *Si* strip detectors
  - 12 vertical strips
    - 3.75 mm pitch
    - 500  $\mu\text{m}$  thick
  - Uniform dead layer  $\approx 1.5 \mu\text{m}$

# Proton Recoil Measurement

Expected elastic signal

Simple toy simulation with bunch length 3 ns

Non-relativistic:  $T_{kin} = \frac{1}{2}mv^2$   $\longrightarrow$

Time of flight is used for particle identification

Real measurement

Already includes some basic cuts (low  $E$ , low  $t$ )

# Proton Recoil Measurement

Time of flight is used for particle identification

Recoil angle is used for kinematic correlation in elastic scattering

# Absolute Beam Polarization

$$\varepsilon = A_N \cdot P$$

$$P_{Beam} = - \frac{\varepsilon_{Beam}}{\varepsilon_{Target}} P_{Target}$$

1

Polarization independent background

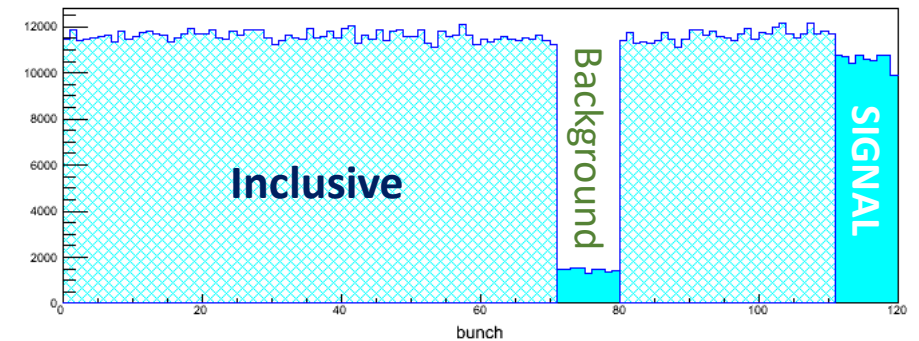

$$\varepsilon = \frac{N^\uparrow - N^\downarrow}{N^\uparrow + N^\downarrow + 2 \cdot N_{bg}} \Rightarrow \frac{\varepsilon_B}{\varepsilon_T} = \frac{N_B^\uparrow - N_B^\downarrow}{N_T^\uparrow - N_T^\downarrow}$$

2

Polarization dependent background

$$\varepsilon = \frac{\varepsilon_{inc} - r \cdot \varepsilon_{bg}}{1 - r}$$

background fraction  $r = N_{bg}/N$

# A Suite of Polarimeters

Hydrogen jet polarimeter

Polarized target

Continuous operation

$\delta P/P \approx 5 - 6\%$  per 8 hours of operation

From our list of requirements:

Time-dependence (polarization decay)

Bunch-by-bunch polarization

Transverse polarization profile of bunches

**Also has to be non-destructive!**

normalization

Carbon polarimeters

Fast measurement

$\delta P/P \approx 4\%$

Beam polarization profile

Bunch-by-bunch

Polarization decay (time dependence)

# Fiber Target Polarimeters

- Ultra-thin ribbon targets:  
     $\approx 10 \mu\text{m} \times 100 \text{nm}$
- Target holder inside the beam pipe

# Polarization Decay

Polarization losses during the store are correlated to

- acceleration
- emittance
- profile

$$P = P_0 + \frac{dP}{dt} t$$

$$P_{jet} = \frac{\int dx dy P(t) I_B(t)}{\int dx dy I_B(t)}$$

normalization with HJET

# Polarization Decay

Polarization losses during the store are correlated to

- acceleration
- emittance
- profile

$$P = P_0 + \frac{dP}{dt} t$$

$$P_{coll} = \frac{\int dx dy P(t) I_B(t) I_Y(t)}{\int dx dy I_B(t) I_Y(t)}$$

$$P_{jet} = \frac{\int dx dy P(t) I_B(t)}{\int dx dy I_B(t)}$$

Important for experiments:  
Luminosity changes throughout each store

# Polarization Profile

Polarization losses during the store are correlated to

- acceleration
- emittance
- profile

$$P = P_0 + \frac{dP}{dt} t$$

$$R = R_0 + \frac{dR}{dt} t$$

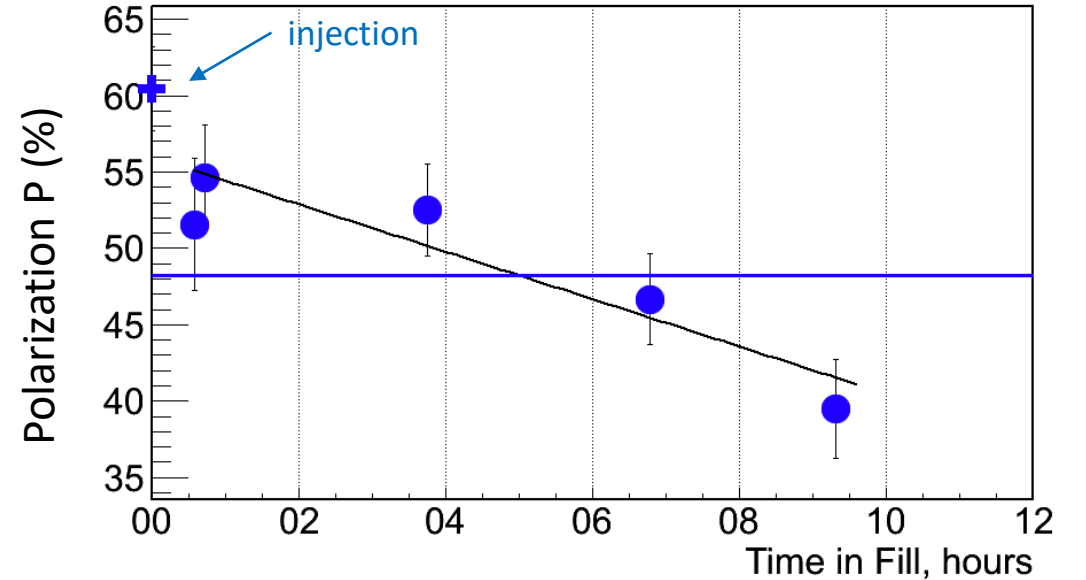

$$P_{coll} = \frac{\int dx dy P(x, y) I_B(x, y) I_Y(x, y)}{\int dx dy I_B(x, y) I_Y(x, y)}$$

$$P_{jet} = \frac{\int dx dy P(x, y) I_B(x, y)}{\int dx dy I_B(x, y)}$$

$$P_{sweep} = \frac{\int dy P(y) I_B(y)}{\int dy I_B(y)}$$

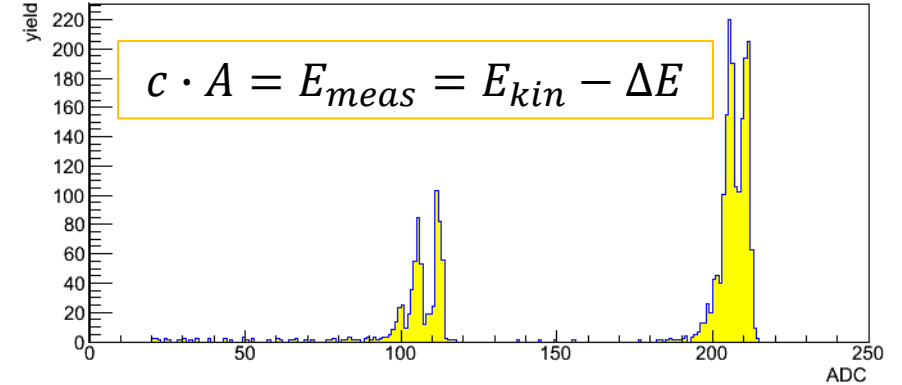

# Limitations of the Measurement

- Recoil particles have very low energy.
  - significant impact of the inactive detector parts (dead layer  $\Delta E$ ), especially for the Carbon measurement
  - Calibration with  $\alpha$ -sources

$$^{148}\text{Gd}(E_\alpha = 3.183 \text{ MeV})$$

$$^{243}\text{Am}(E_\alpha = 5.486 \text{ MeV})$$

- Small angle scattering of recoil inside the target dilutes the kinematic correlation for elastic scattering.
  - Background dilutes the measured asymmetry (increases statistical uncertainty), but normalized with HJET
  - $A_N$  drops above 1 MeV

# Target Lifetime

- High energy, high intensity proton beams provide an extreme environment
  - Energy loss of beam in the target
- Target is electrostatically attracted to the beam
  - Mechanical stress on target
  - Material in beam is hard to control
- Induced charge from wake field on target ends
  - Change to insulated ladder construction
- Targets have a limited lifetime

Simulation by J. Kewisch, BNL

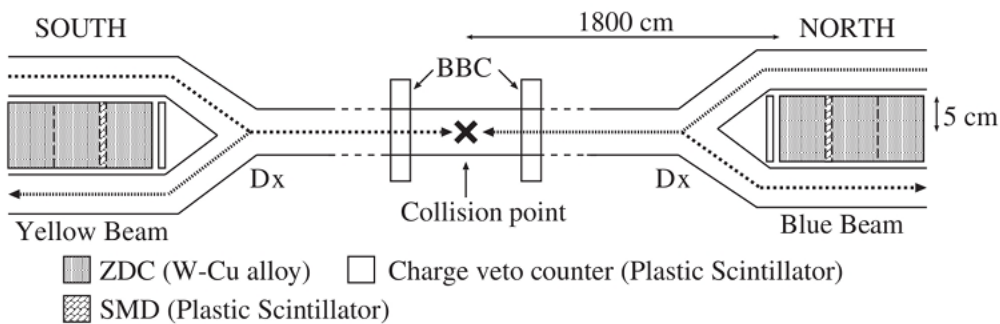

# Local Polarimetry at RHIC

- Local polarimetry is primarily for confirming the direction of the polarization vector at the experiment.
  - Observe suppression of asymmetry or change of direction
  - Very forward going production of neutrons in  $p + p$  collisions
  - First established at RHIC-IP12, standard method for RHIC experiments

$$x_F = 2p_z / \sqrt{s}$$

# Potential for Future Applications

- Nuclear dependence of very forward going neutrons
  - Very large asymmetry (with opposite sign)
  - Select low multiplicity with beam-beam counters
  - Ultra-peripheral collision extension to  $\pi/a_1$  model
  - Photon flux from STARlight  
Klein et al., Comput. Phys. Comm. 212 (2017) 258
  - $\gamma + p \rightarrow n + \pi^+$  from MAID  
Drechsel et al., Eur. Phys. J. A 34 (2007) 69

$p^\uparrow + p$   
 $p^\uparrow + Al$   
 $p^\uparrow + Au$

Phys. Rev. Lett 120 (2018) 022001  
 Phys. Rev. C 95 (2017) 044908

# From RHIC to EIC

↕ Bunch length  
↔ Detector resolution

120 bunches → 1320 bunches  
Bunch spacing 106 ns → 9.6 ns  
Bunch length 3.5 ns → 0.3 ns

# From RHIC to EIC

- Loss of increased asymmetry at lower energies,  $A_N(-t)$
- Reduced bunch spacing requires much better understanding of background
  - Polarized or unpolarized
  - Better: reject/suppress background
  - Second detector layer to veto high energy particles

# From RHIC to EIC

- Loss of increased asymmetry at lower energies,  $A_N(-t)$
- Reduced bunch spacing requires much better understanding of background
  - Polarized or unpolarized
  - Better: reject/suppress background
- Increased beam current is problematic for the fiber target
  - Very limited cooling (radiation, thermal conductivity)
  - Sublimation temperature  $T_{Carbon} \approx 2200^\circ C$
  - Temperature saturates in a few ms

Can we find a target material that withstands higher temperatures?

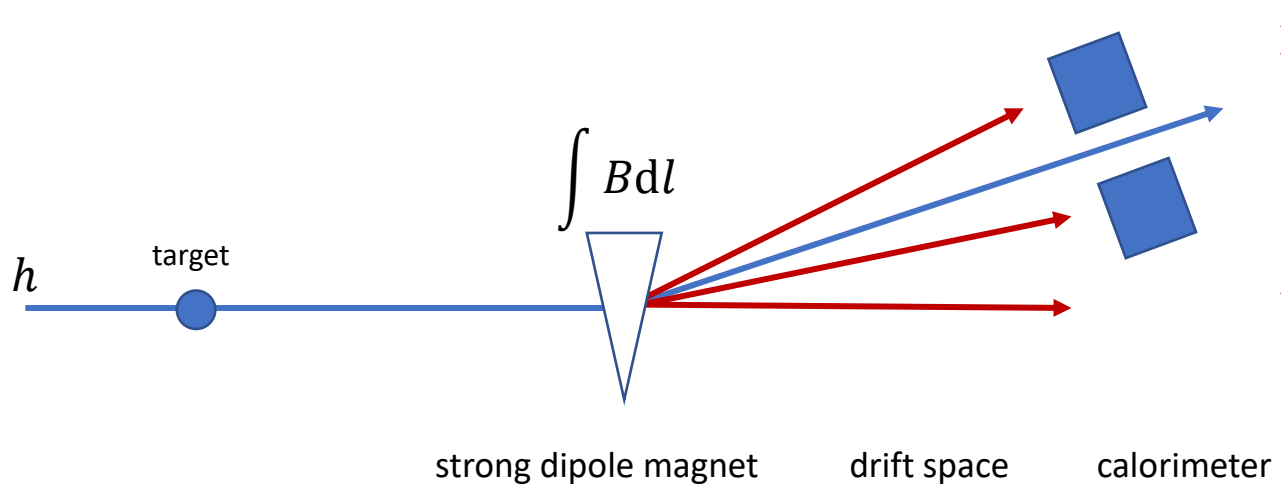

# Polarized Light Ion Beams

- Polarized  $d$  and  ${}^3He$  beams are not part of the EIC baseline design.
- Absolute polarization will (likely) require a polarized  ${}^3He$  target.

- Elastic scattering is necessary for the sign-flip of the analyzing power

$$A_{00N0} = -A_{000N}$$

- Breakup energy is only 5.5 MeV: problematic if beam breaks up  $h \rightarrow pd$
- Tag/veto breakup products downstream of the polarimeter

- $p: e/m = 1$
- $h: e/m = 2/3$
- $d: e/m = 1/2$
- $n: e/m = 0$

threshold for  $pp \rightarrow ppp\pi$

# Recap: Hadron Polarimetry

- Proton beam energies: 50 – 275 GeV
- Combination of devices for
  - Non-destructive
  - Absolute polarization
  - Fast measurements during store
  - Bunch profile
  - Local polarimetry at experiment
- Potential for future polarized light ion beams
  - Location allows for upgrades to the polarimeter setup

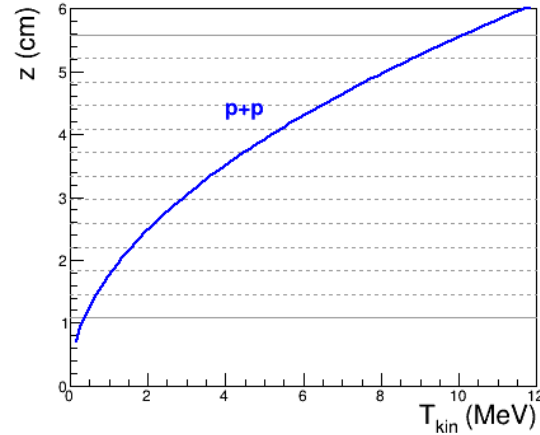

# Backup

# Toy Simulation

- Recoil angle calculated from kinetic energy
- Assume fairly slow exponential cross section as function of energy
- Deposited energy from punch through particles calculated with empirical model (NIST)
- Size of atomic beam target and molecular component
- Effect of opposite beam (upstream contribution from molecular target)

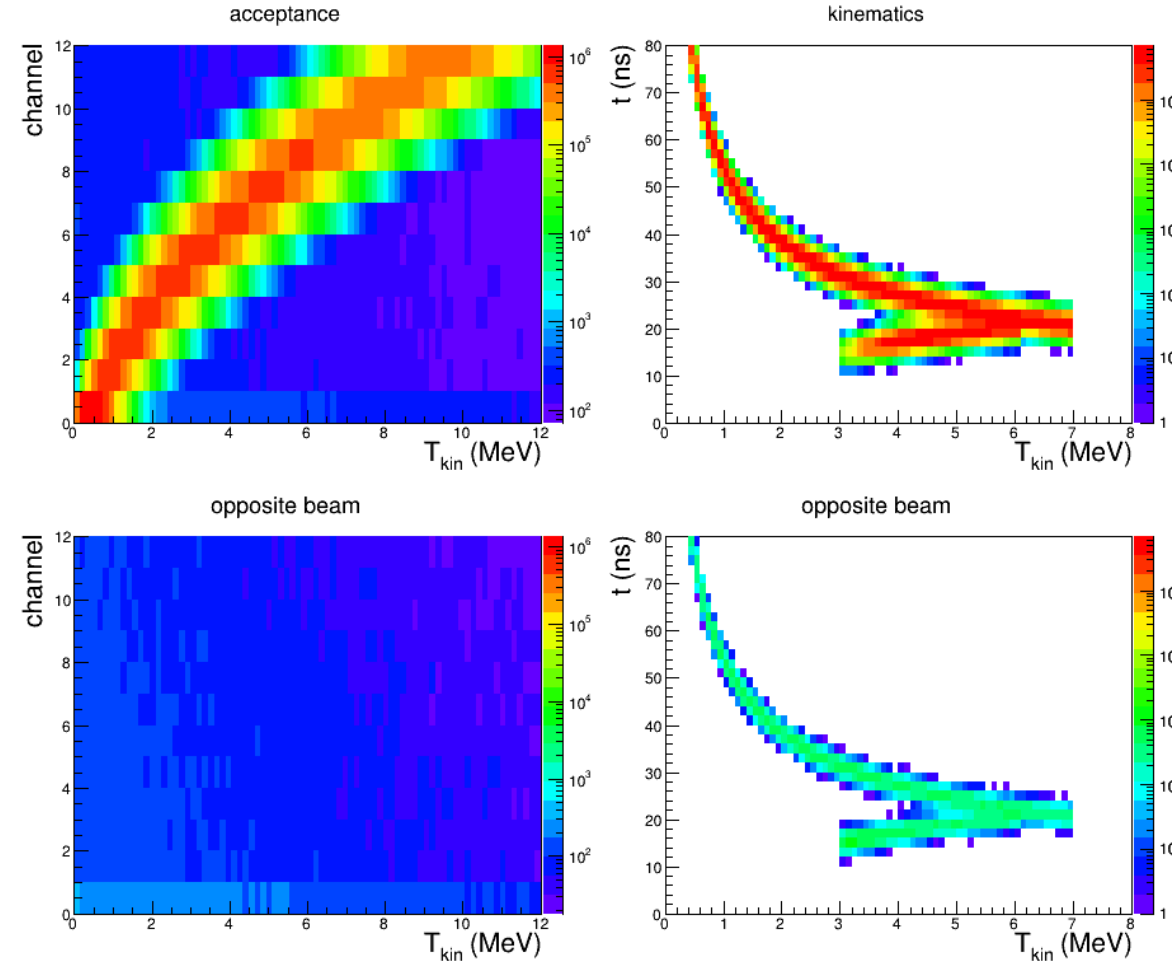

**bunch length  $\sigma_B = 1.0$  ns**  
**target width  $\sigma_T = 0.3$  cm**  
**molecular width  $\sigma_M = 9.0$  cm**  
**molecular fraction  $r = 1\%$**

Main uncertainties:

- Bunch length
- Target thickness ( $z$ )
- Molecular background ( $z$ )

Other uncertainties:

- Energy resolution
- Strip pitch

# PYTHIA Studies

- p+p at  $\sqrt{s} = 21.6$  GeV with boost
  - Equivalent to 250 GeV beam on fixed target
- PYTHIA 6.4.28, Tune 320
  - QCD  $2 \rightarrow 2$
  - Elastic
  - Diffractive
- Fast background
  - pions, (*photons*) up to a few GeV
  - Kinematic correlation lost
- For this study, the vertical size of the detector is not relevant (no asymmetry measurement, keep full azimuthal range  $\varphi$ )

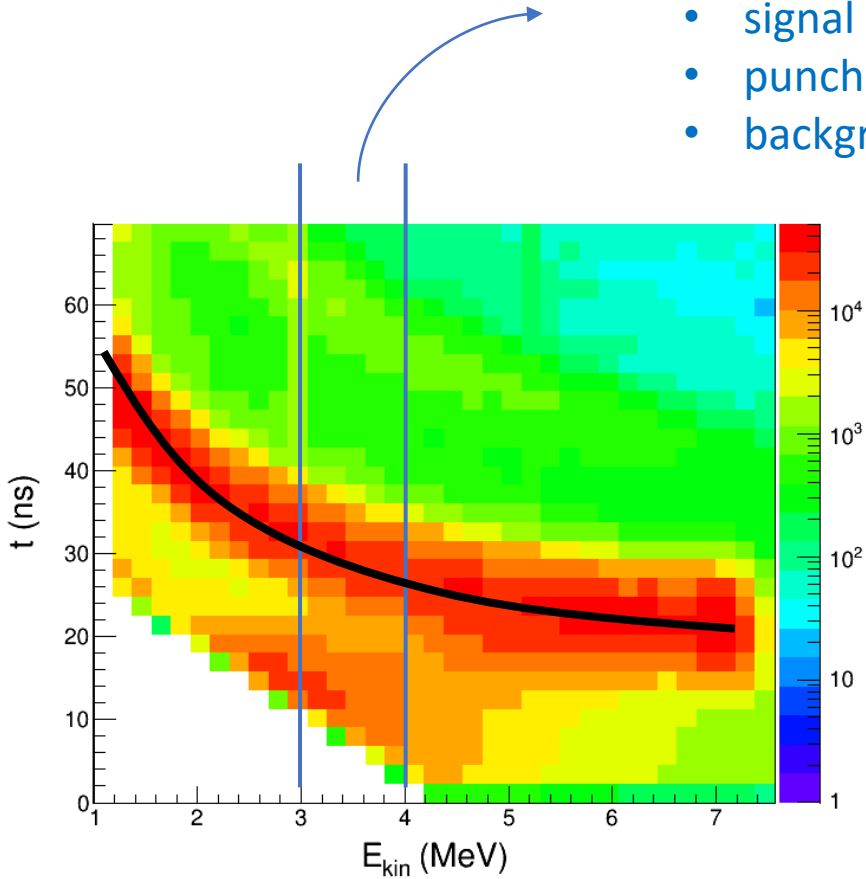

upstream    downstream

Combine signal and background into time-of-flight vs. deposited energy

# How to quantify the background

- Slice in kinetic energy
- Compare
  - signal
  - punch through
  - background

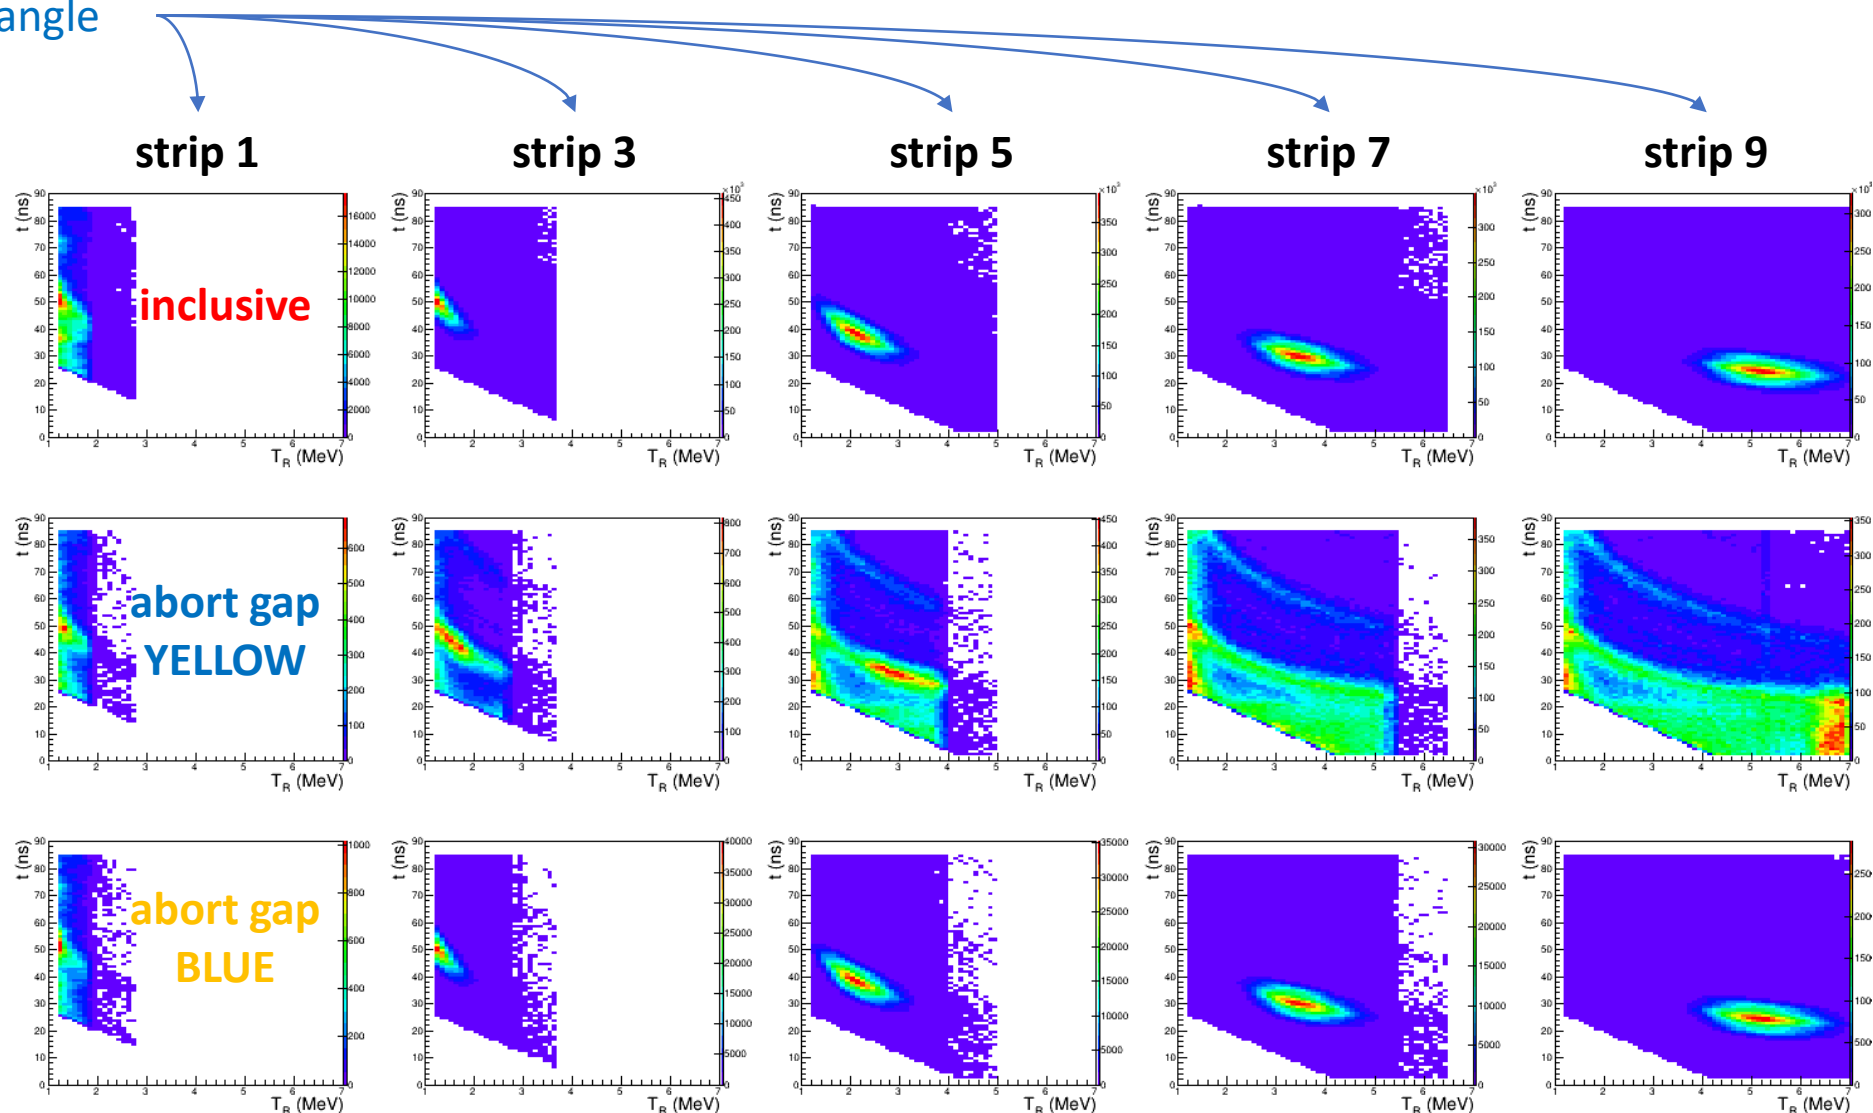

$$\Delta t = t_{\text{meas}} - t_{\text{calc}}$$

	$m_{\text{miss}} \approx m_p$	$m_{\text{miss}} \neq m_p$
Inclusive	●	○
Abort gap	○	
Signal		●

# Kinematics of the Recoil Proton

different recoil angle

DST files are available with jetTree:

- tof
- ekin
- strip ( $\alpha$ )

Will need to rerun a few fills without the manual tof/ekin cut

# Polarimeter Simulation

37

- Full detector in GEANT4
  - 400  $\mu\text{m}$  Silicon, 8  $\mu\text{m}$  dead layer
  - No strip segmentation (no pile-up seen in data)
- Detector chamber and flanges
- Atomic hydrogen jet target
  - $\rho \approx 0.4 \cdot 10^{-11} \text{ g/cm}^3$
- Parameterized magnetic holding field
- Beam bunch length (3.5 ns)
- Vertex distribution (5 mm, 10 cm)
- PYTHIA input
  - Single beam

# Simulation Results

- 100M + 10M filtered PYTHIA events
  - Tracks within  $30^\circ$  of detector center
  - About 2M + 250k hits
  - Rarely more than one track per event
- Simulation reproduces the basic features
  - Kinematic correlation (elastic scattering)
  - Signal and background (particle id)

# Simulation Results

- Punch-through particles
  - Fast, little energy deposit
- Very few recoil protons in upstream detector
  - Compare target width with detector length
- Contribution from widely distributed molecular hydrogen
  - Wide range of punch-through particles
  - Skewed vertex distribution due to detector acceptance
- Test measurements in RHIC Run 2022
  - Modifications to detector setup to veto punch-through particles
