Machine Learning Based Accelerator Control

Goals:

- Automate routine tasks + improve performance
- Enable new capabilities

Challenges:

- Practical constraints and complexities of realistic accelerators
- Incorporating prior knowledge
- Scaling

Controlling Beam Optics with Electromagnets

Electron beam

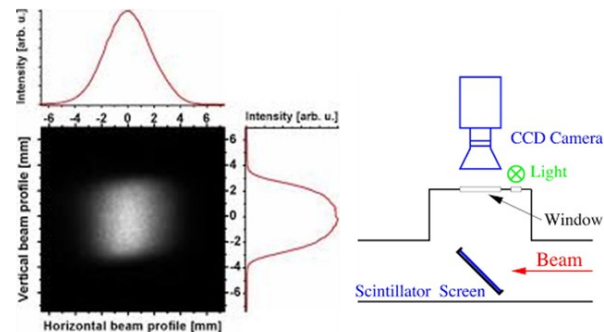

Quadrupole (focusing) magnets

standard quadrupole

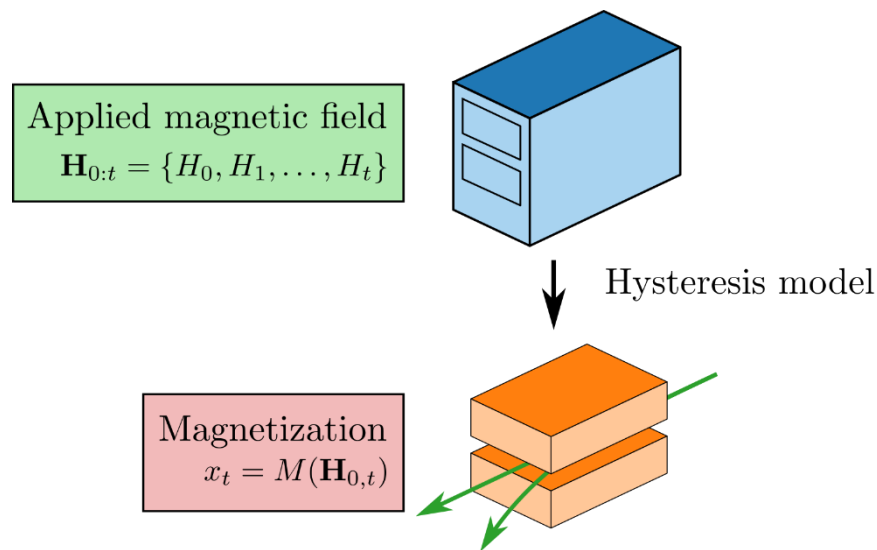

Insertable diagnostic screens

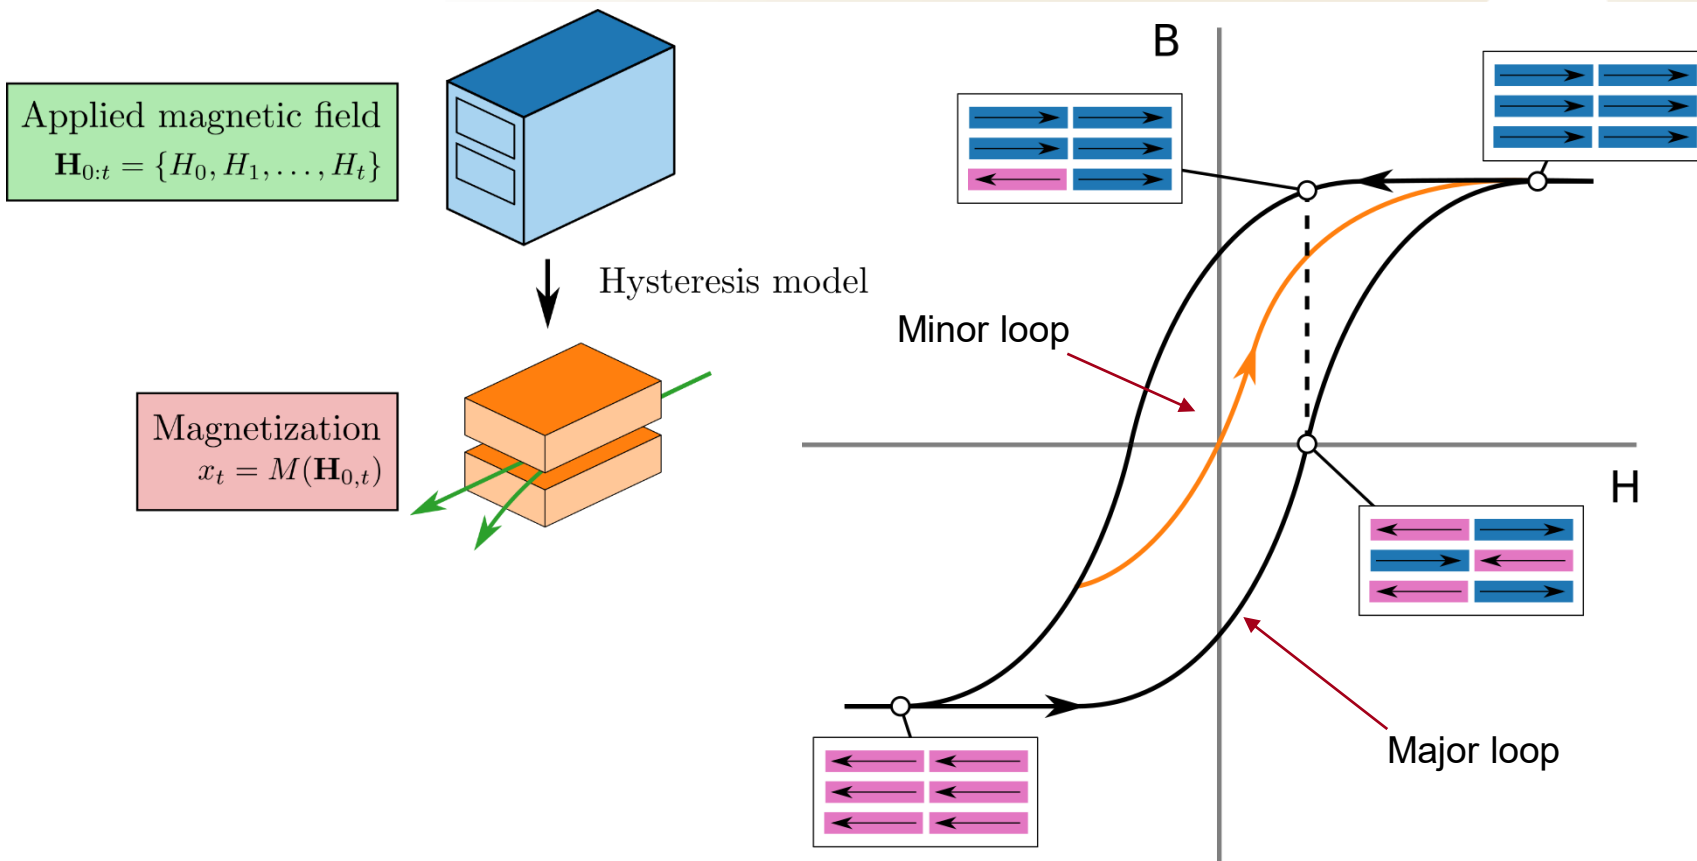

Modeling Hysteresis Effects in Accelerators

We generally only have control over applied currents to magnetic elements

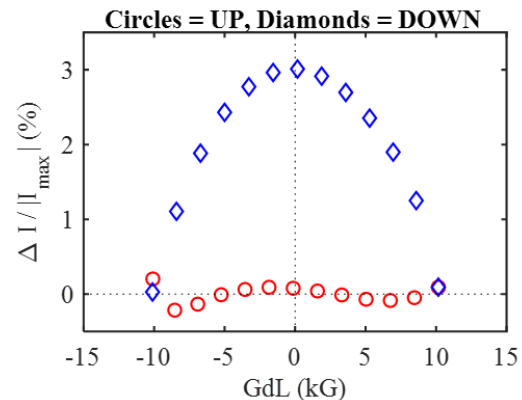

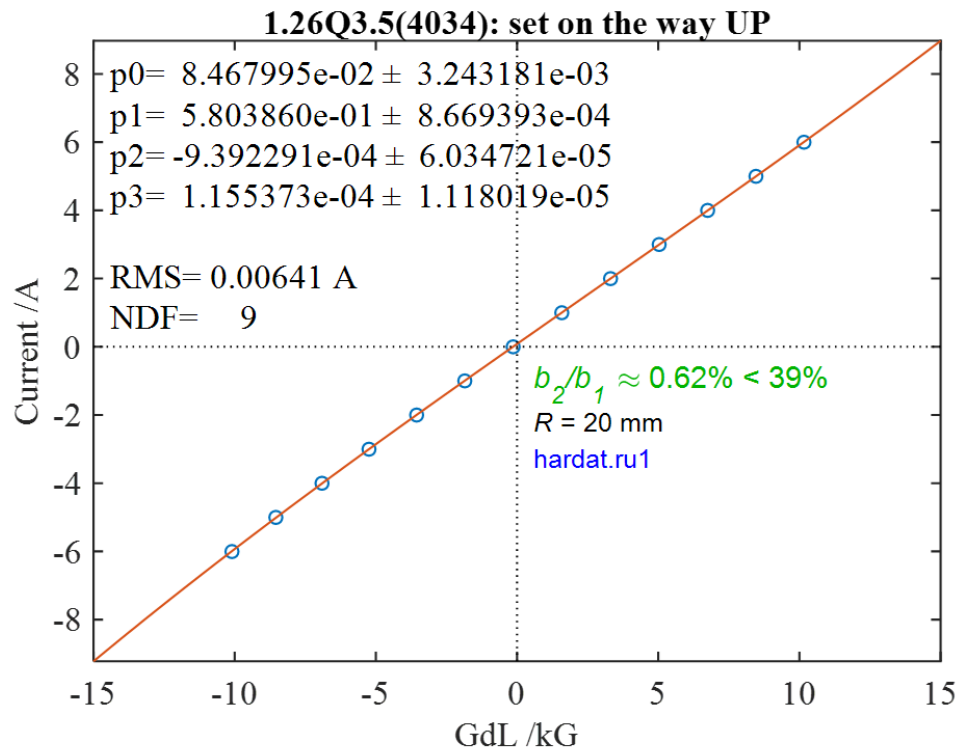

- Current optimization schemes ignore hysteresis effects
- Need to develop a fast-modeling strategy to improve online control without measuring the hysteresis curve directly

Hysteresis Effects in Electromagnets

Realistic Accelerator Magnets

The Preisach Model for Hysteresis

Model magnetic domains as individual “hysterons”

Determine the hysteron density

Determine hysteron states via history of applied fields

$$M(\mathbf{H}_{0:t}) = \int_{S_+} \mu(\beta, \alpha) d\beta d\alpha - \int_{S_-} \mu(\beta, \alpha) d\beta d\alpha$$

Parametric Preisach Modeling

$$\mu(\alpha, \beta) = f(\alpha, \beta; \theta)$$

$$\mu_{\text{DAT}}(\alpha, \beta) = \frac{A}{1 + \{[(\alpha + \beta)\sigma]^2 + [(\alpha - \beta - h)\sigma]^2\}^\eta}$$

Non-parametric Preisach Modeling

Limited by
model
selection

$$\mu(\alpha, \beta) = f(\alpha, \beta; \theta) \quad \rightarrow \quad \mu_i = \mu(\alpha_i, \beta_i)$$

However, this greatly increases the number of free parameters.
How to solve?

Differentiable Non-parametric Preisach Modeling

Keep track of derivative information during **every** calculation step.

Enables **gradient based optimization** of model error with respect to all free parameters using the chain rule.

Easily optimize models with ~10k free parameters.

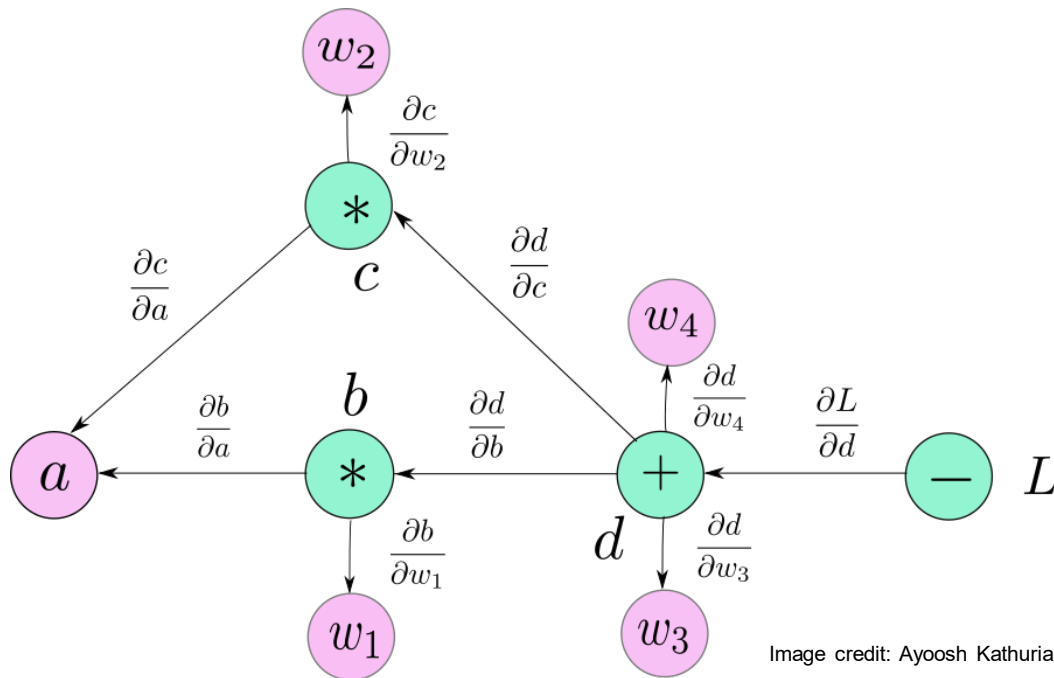

Image credit: Ayoosh Kathuria

Simple Example

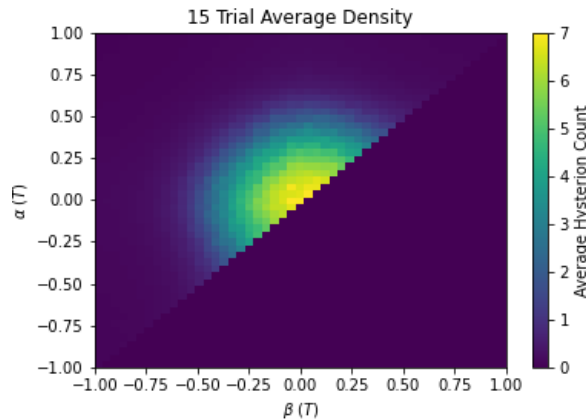

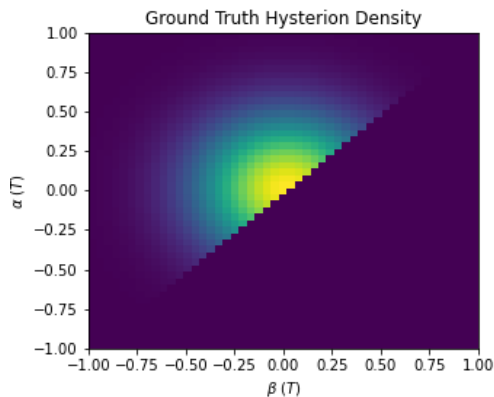

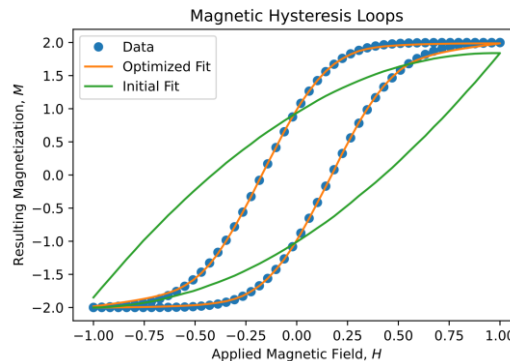

Discretize the space into $n \times n$ grid and treat the density at each grid point as a free parameter

$$\boldsymbol{\mu} = \{\mu_1, \mu_2, \dots, \mu_N\}$$

$$M(H_{0:t}; \boldsymbol{\mu}) = \sum_{i=1}^N \mu_i \gamma_i(H_{0:t})$$

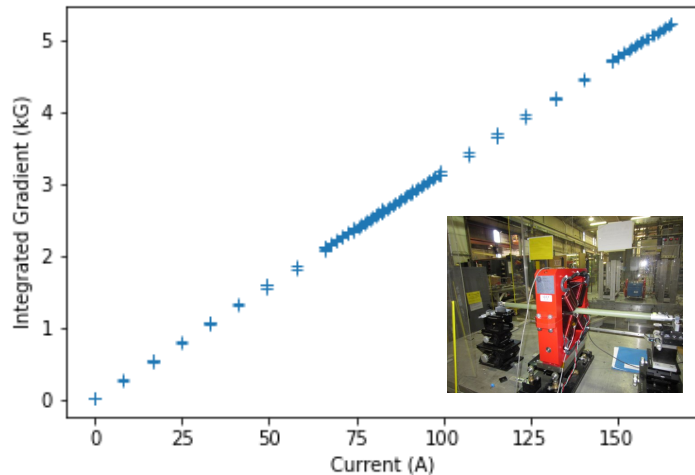

$$loss(\boldsymbol{\mu}) = \text{MSE}(Y, M(H; \boldsymbol{\mu}))$$

$$\boldsymbol{\mu}^* = \text{argmin}_{\boldsymbol{\mu}} loss(\boldsymbol{\mu})$$

Modeling SLAC Quadrupole Magnets

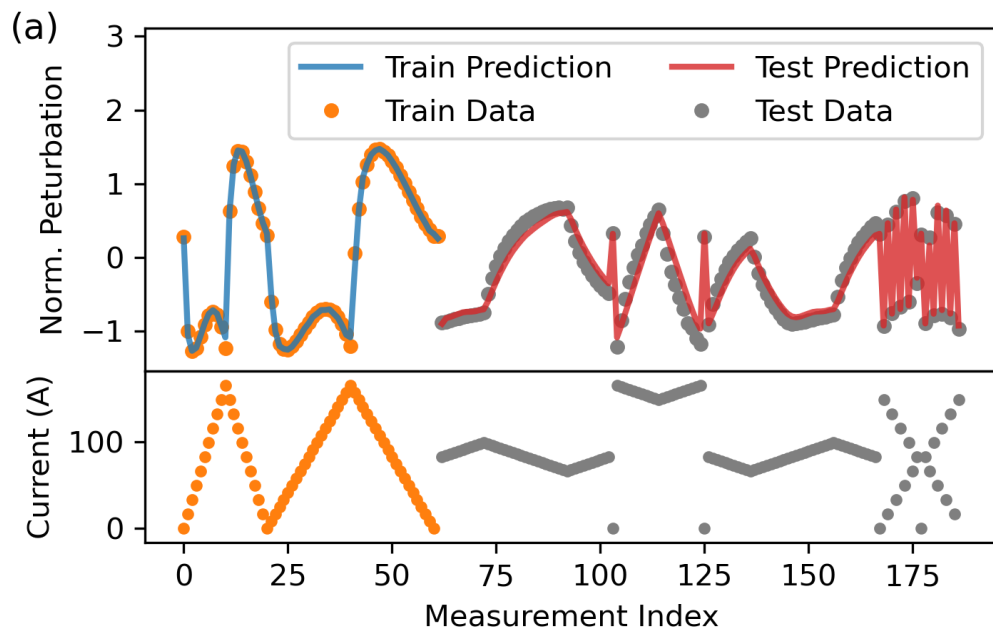

Measured integrated gradient

Normalized Deviation

Modeling SLAC Quadrupoles

Polynomial fit error: 0.23%

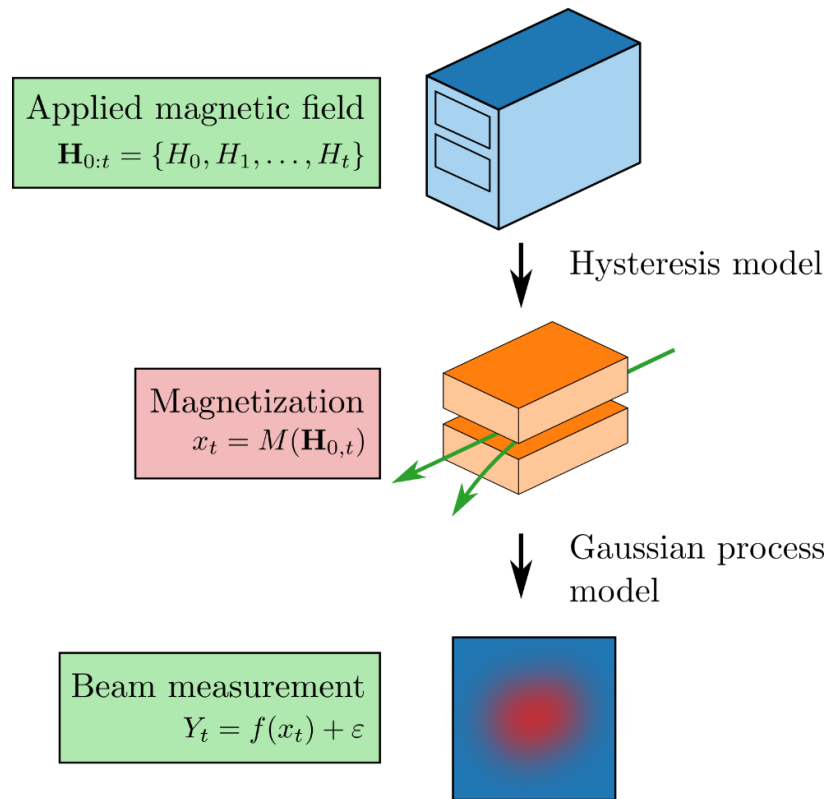

Train error: 0.015%

Test error: 0.051%

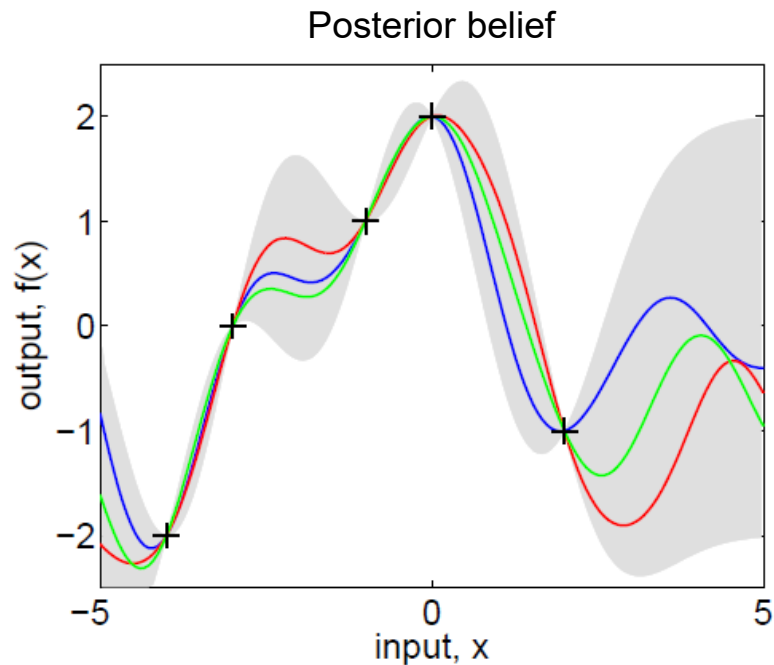

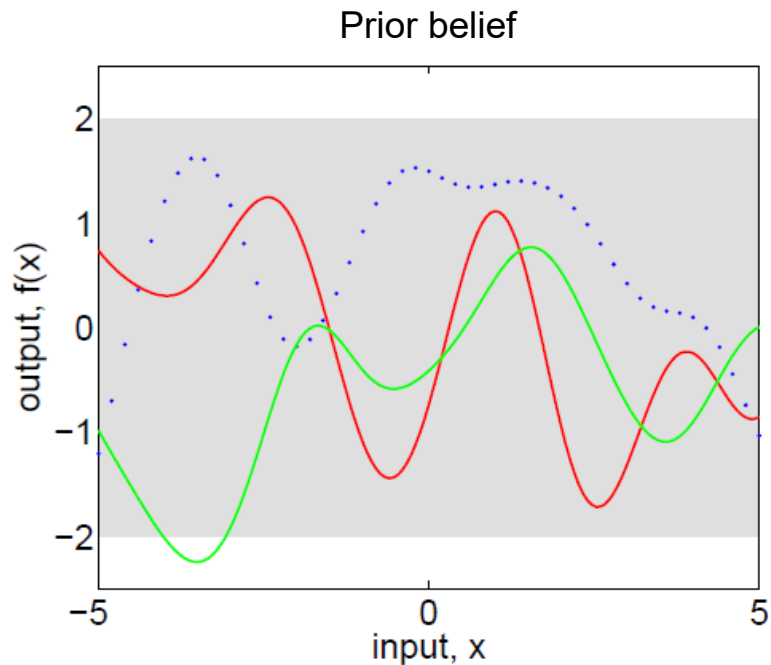

Can we extend this process to modeling magnets **in the beamline already?**

Combine the hysteresis model with a flexible model for the beam response: a **Gaussian Process**, train both models **simultaneously**

Allows us to measure hysteresis characteristics using **beam-based** measurements

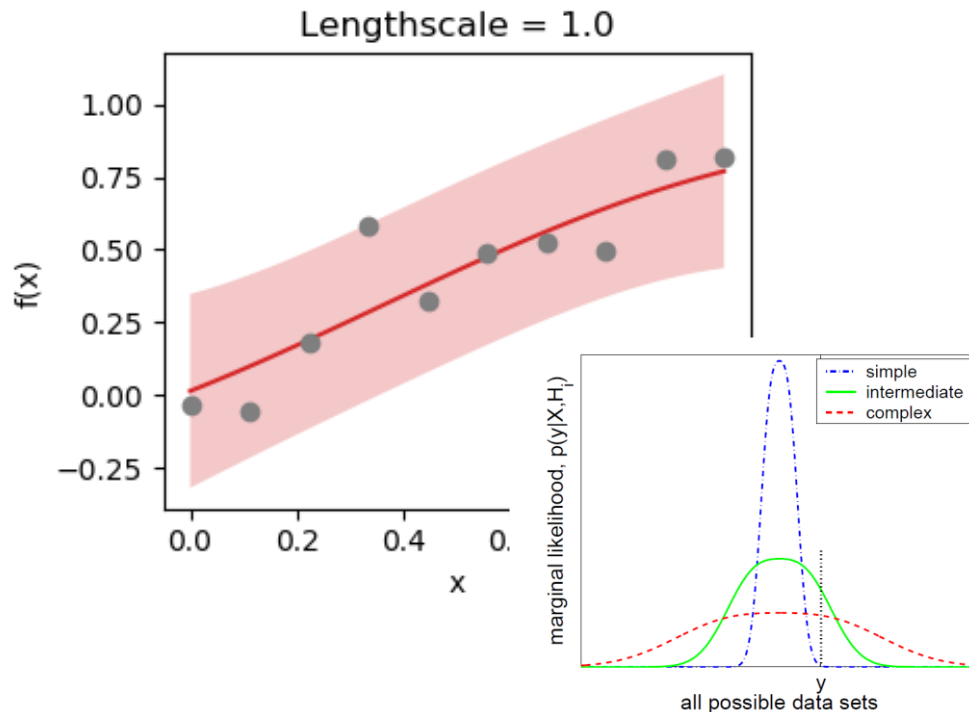

Gaussian Process Surrogate Models

Use Gaussian Processes to represent noisy beam attributes as a function of magnetic fields.

Gaussian Processes - Hyperparameters

Example: APS Injector

Modeling w/o Hysteresis

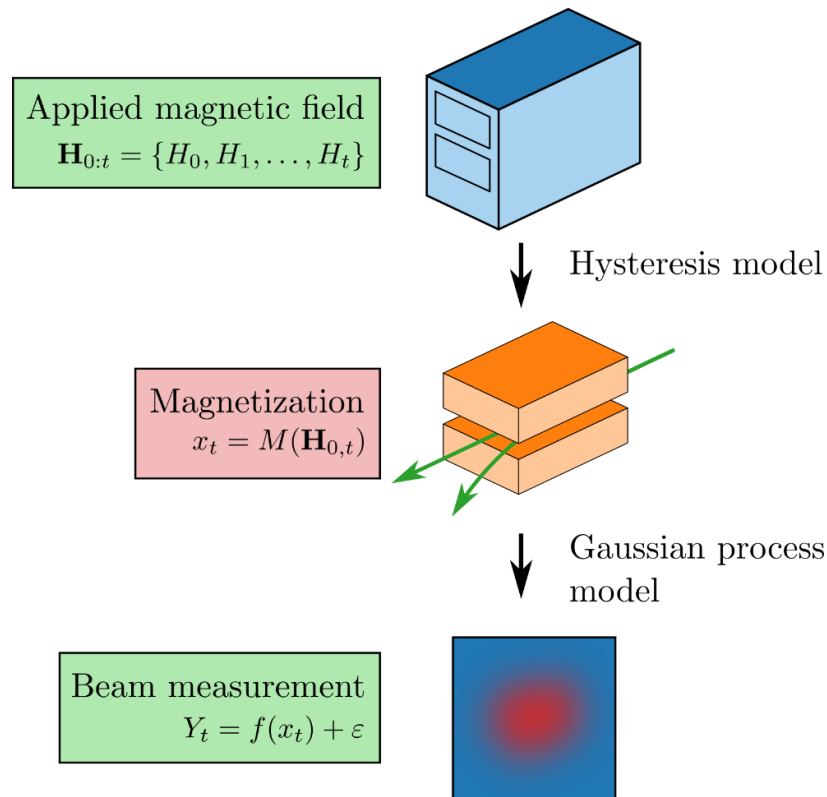

Modeling w/ Hysteresis

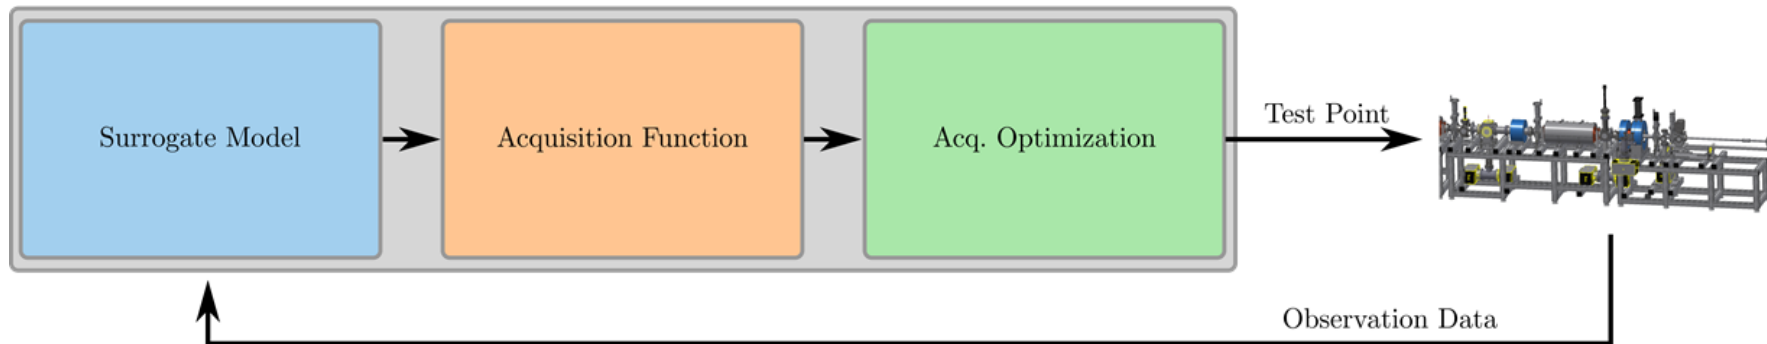

Full Stack Optimization

Now use the joint model to **optimize** accelerator inputs to achieve beam objectives.

Bayesian Optimization Algorithm

Benefits:

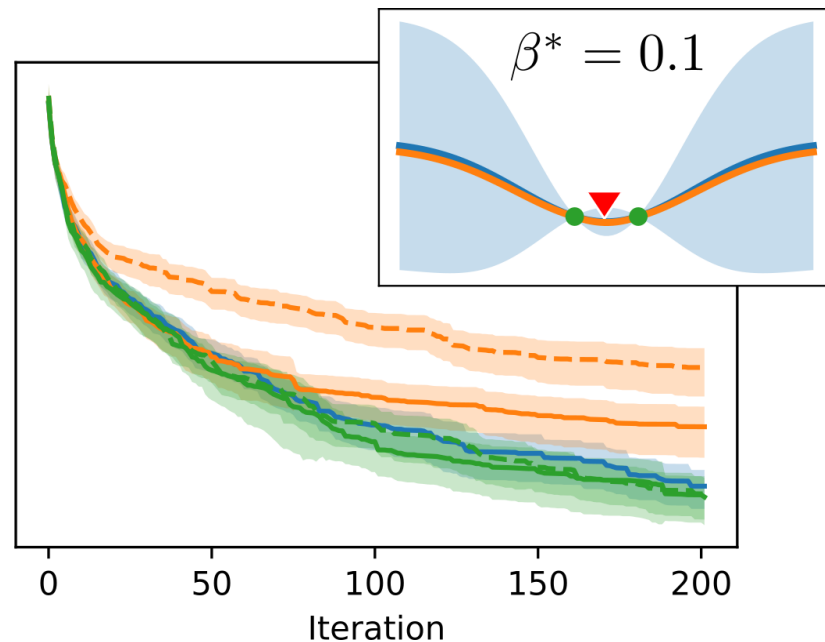

- Specify trade-off between exploration and exploitation
- Inherently improves model accuracy in regions of interest
- Enables serial or parallelized optimization strategies

Beamline Optimization with Hysteresis

Beamline Optimization with Hysteresis

Conclusions

We can create flexible, high-fidelity models of magnetic elements exhibiting hysteresis

We can combine the **hysteresis** and **beam response** models to create a complete model of the beam response as a function of **controllable parameters**.
