EVIDENCE FOR DARK MATTER

non-baryonic

DARK MATTER PROPERTIES

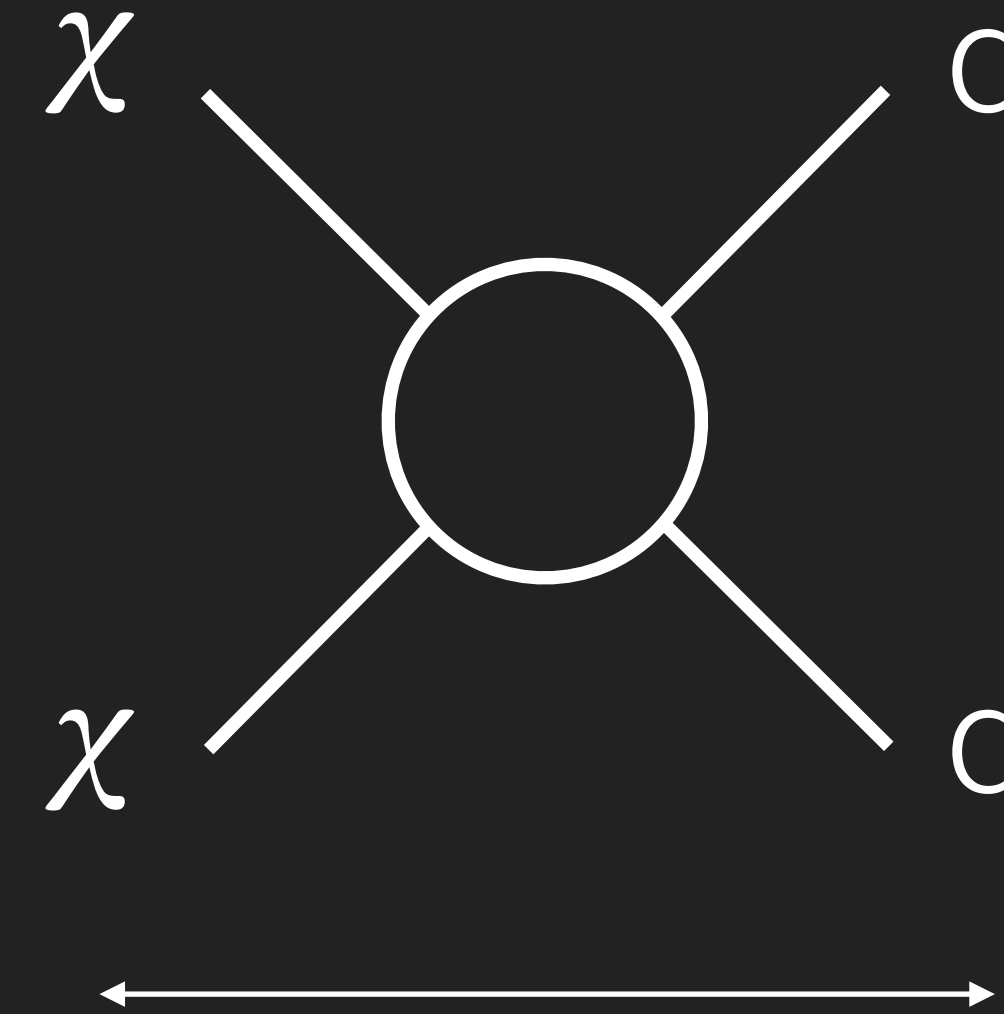

- ▶ Gravitationally interacting
- ▶ Stable particle
- ▶ Not hot
- ▶ Not Baryon

New Physics Beyond Standard Model!!

Weak Interacting Massive Particles (WIMPs) - lightest neutralino?

A WIMP MIRACLE

1. When $T \gg m$, equilibrium
2. When $T < m$, χ decay exponentially.
3. When $\Gamma = H$, χ can not find each other.

$$\Gamma = n(x)\langle\sigma v\rangle \Rightarrow n_f(x) = H/\langle\sigma v\rangle$$

Weak-scale cross section reproduces the expected relic abundance of DM (Λ CDM)

LOCAL DENSITY OF DM

- ▶ Local density of DM, $\rho_{\text{DM}} \sim 0.3 \text{ GeV/cm}^3$

Only mass (energy) density is known.

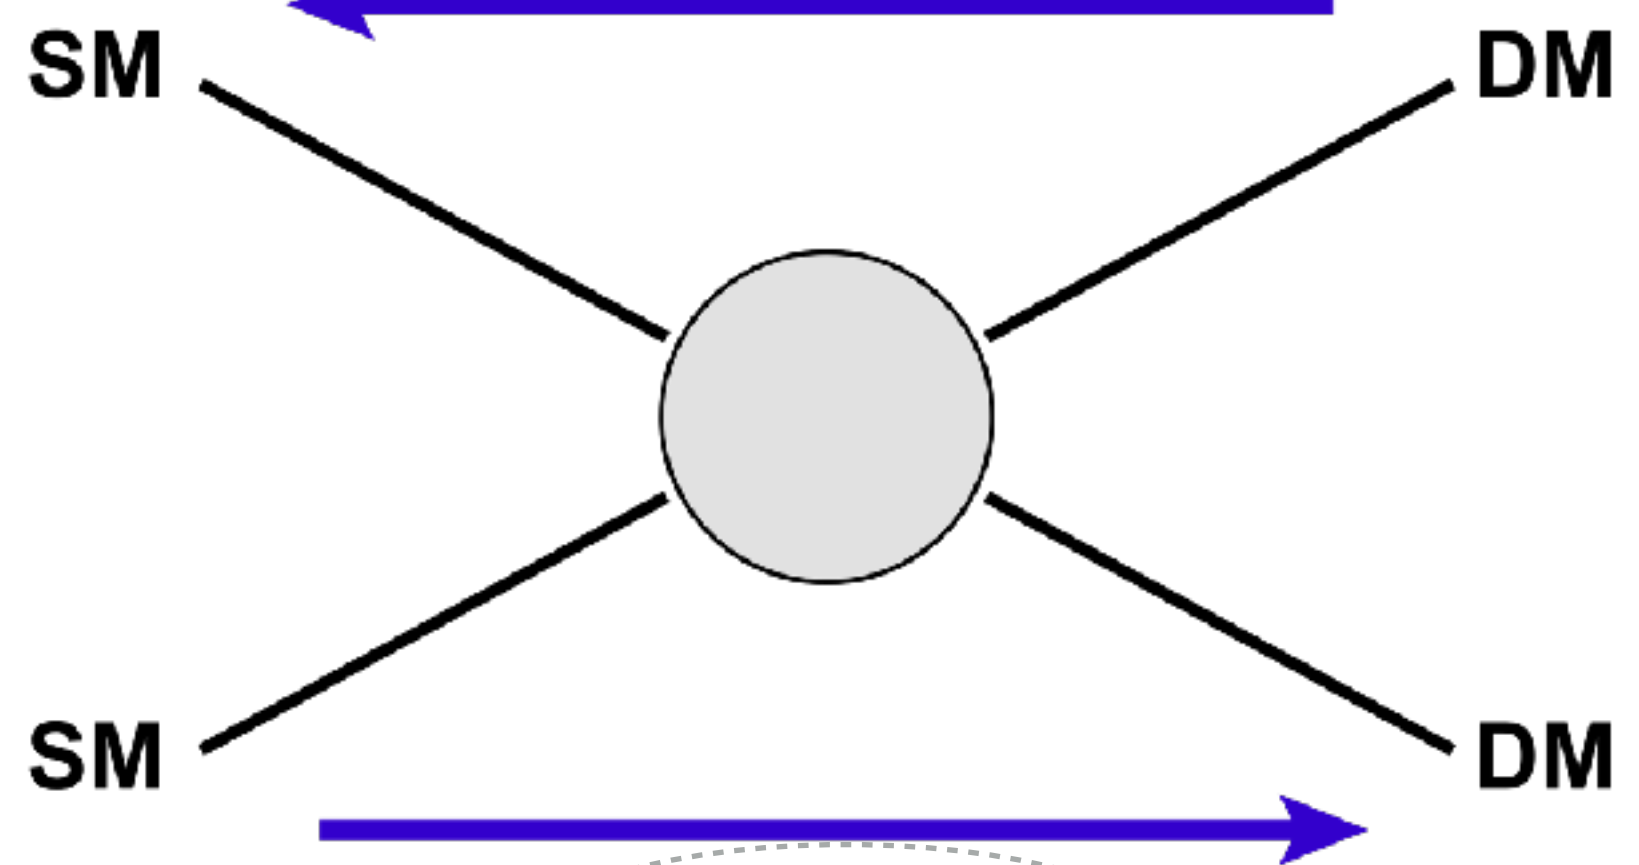

The heavier DM mass, the lower the number density is.

The direct WIMP search is a rare event search.

Direct Detection

Indirect Detection

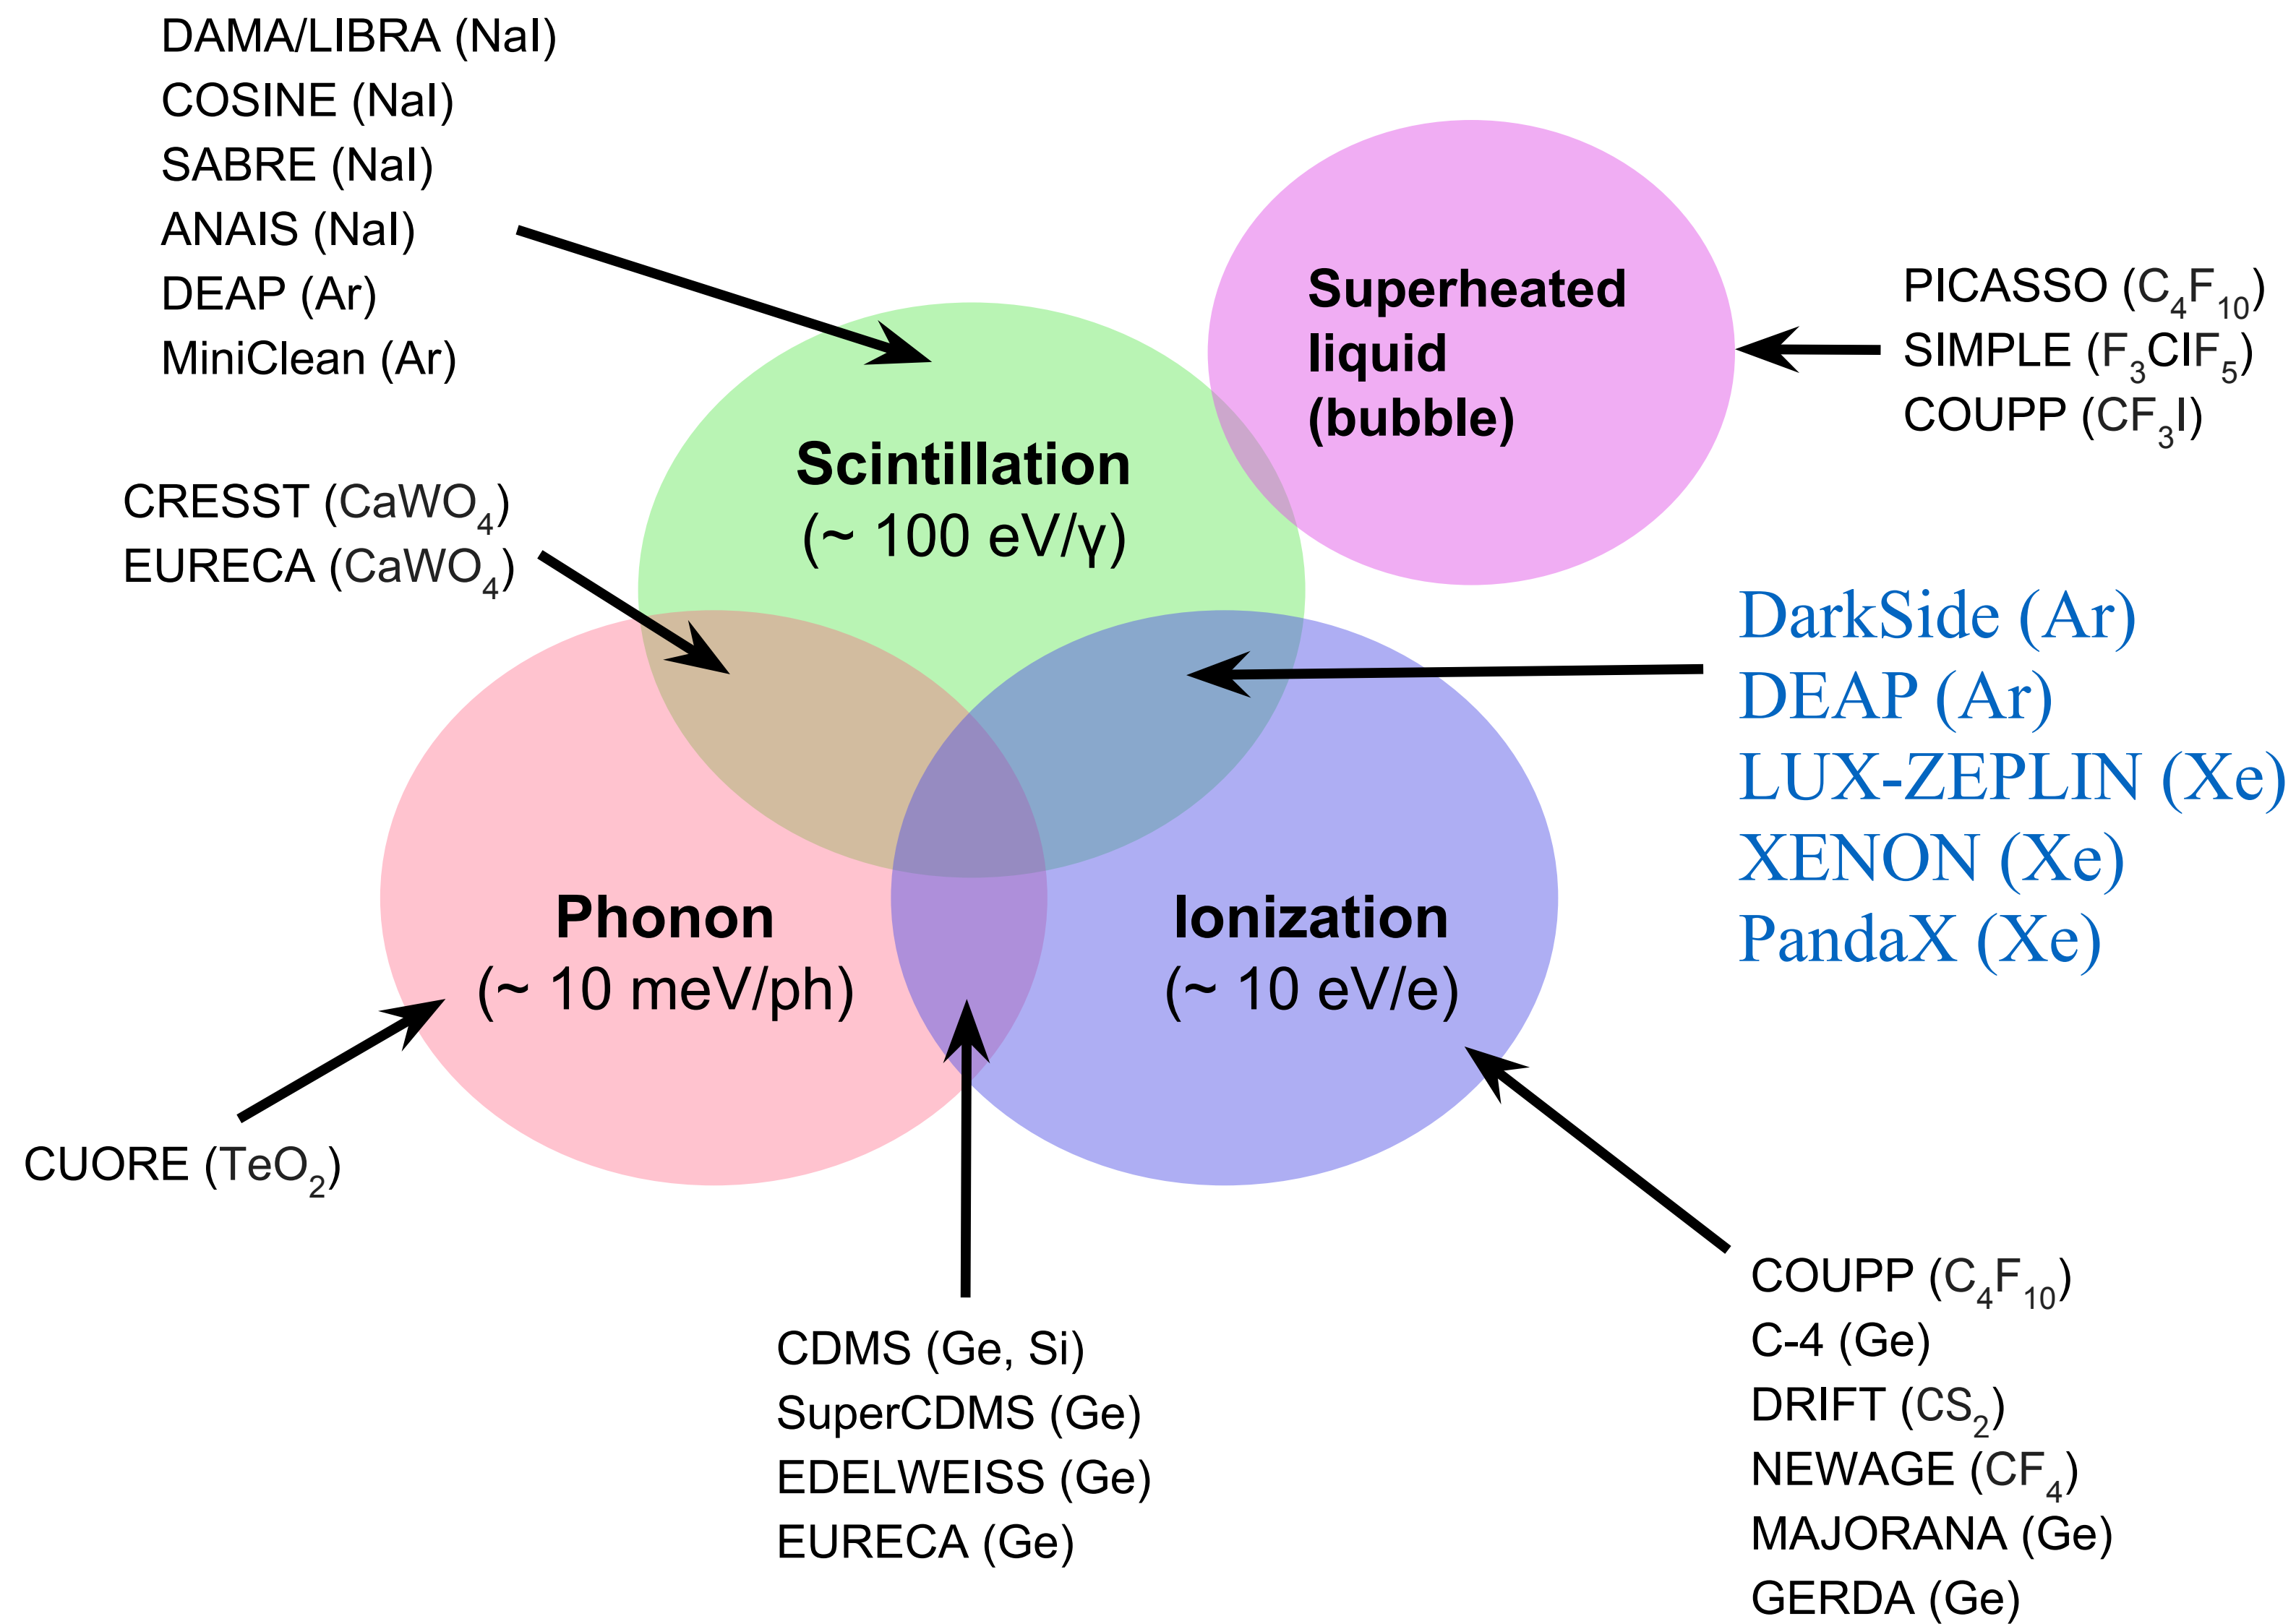

Collider

Direct Detection

Techniques of Direct Detection

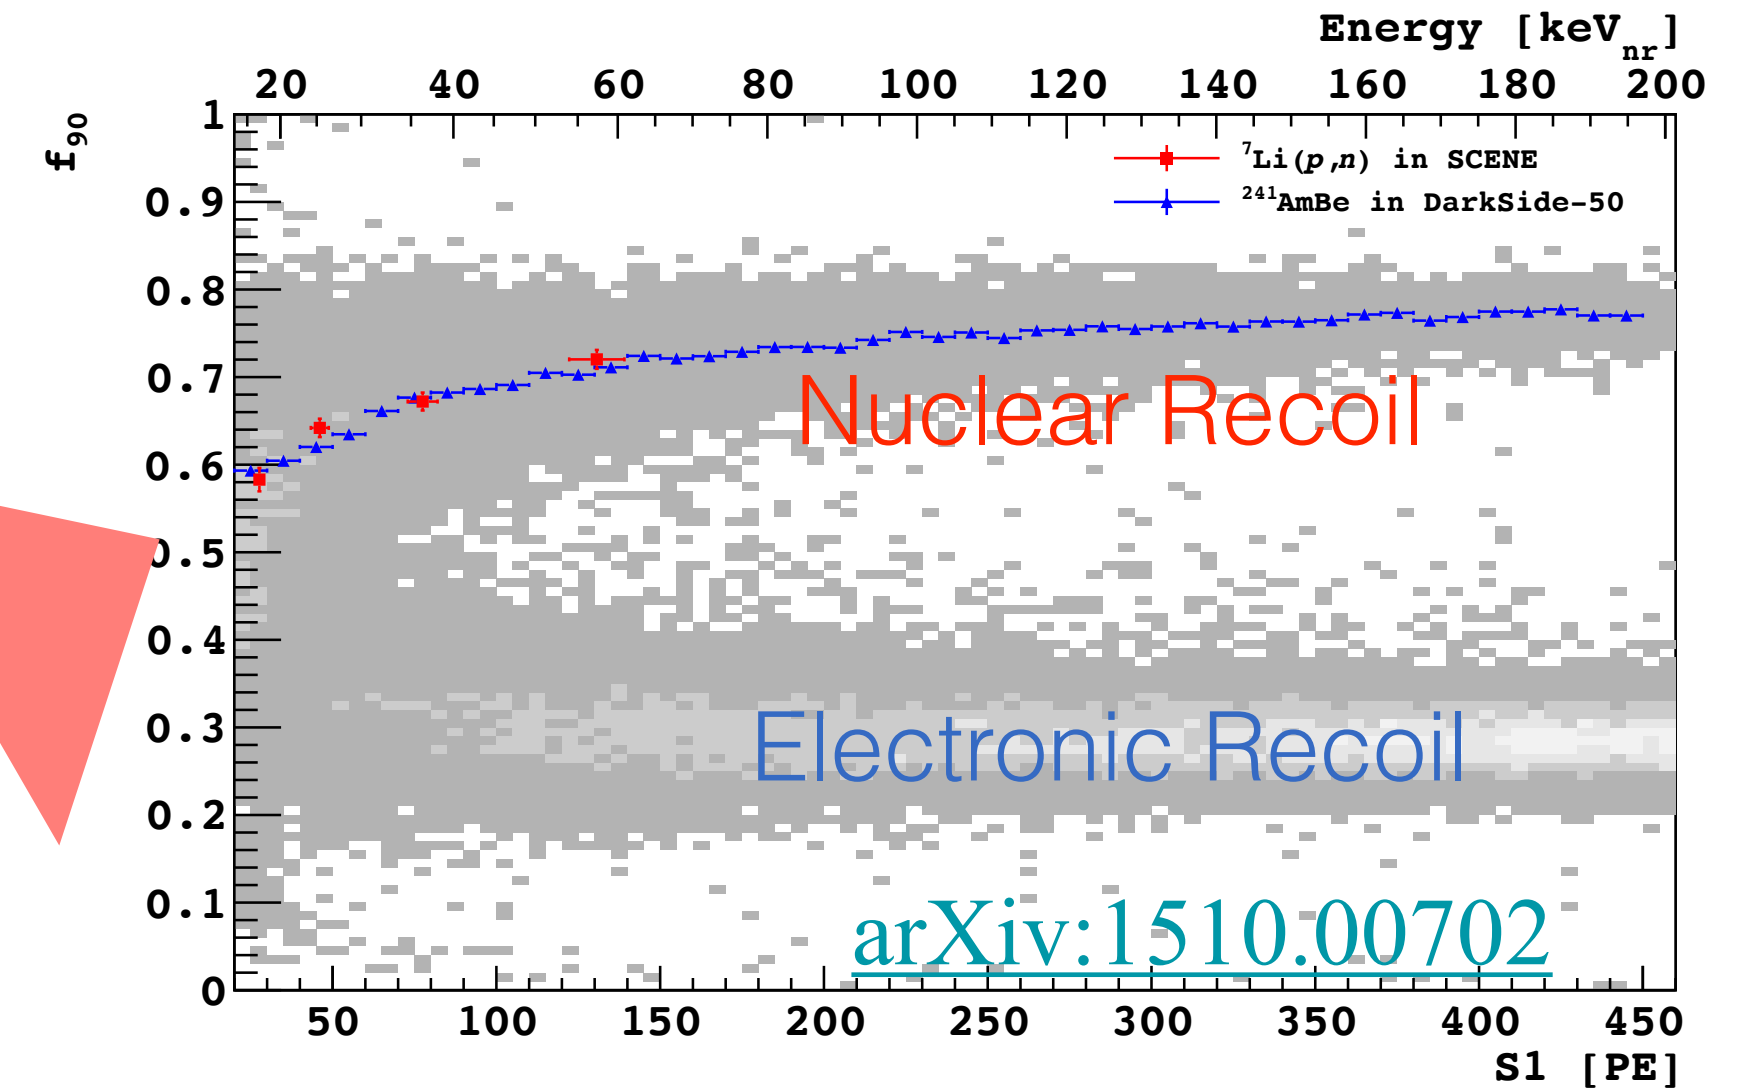

Why Noble Liquid?

Electron Recoil: background-like

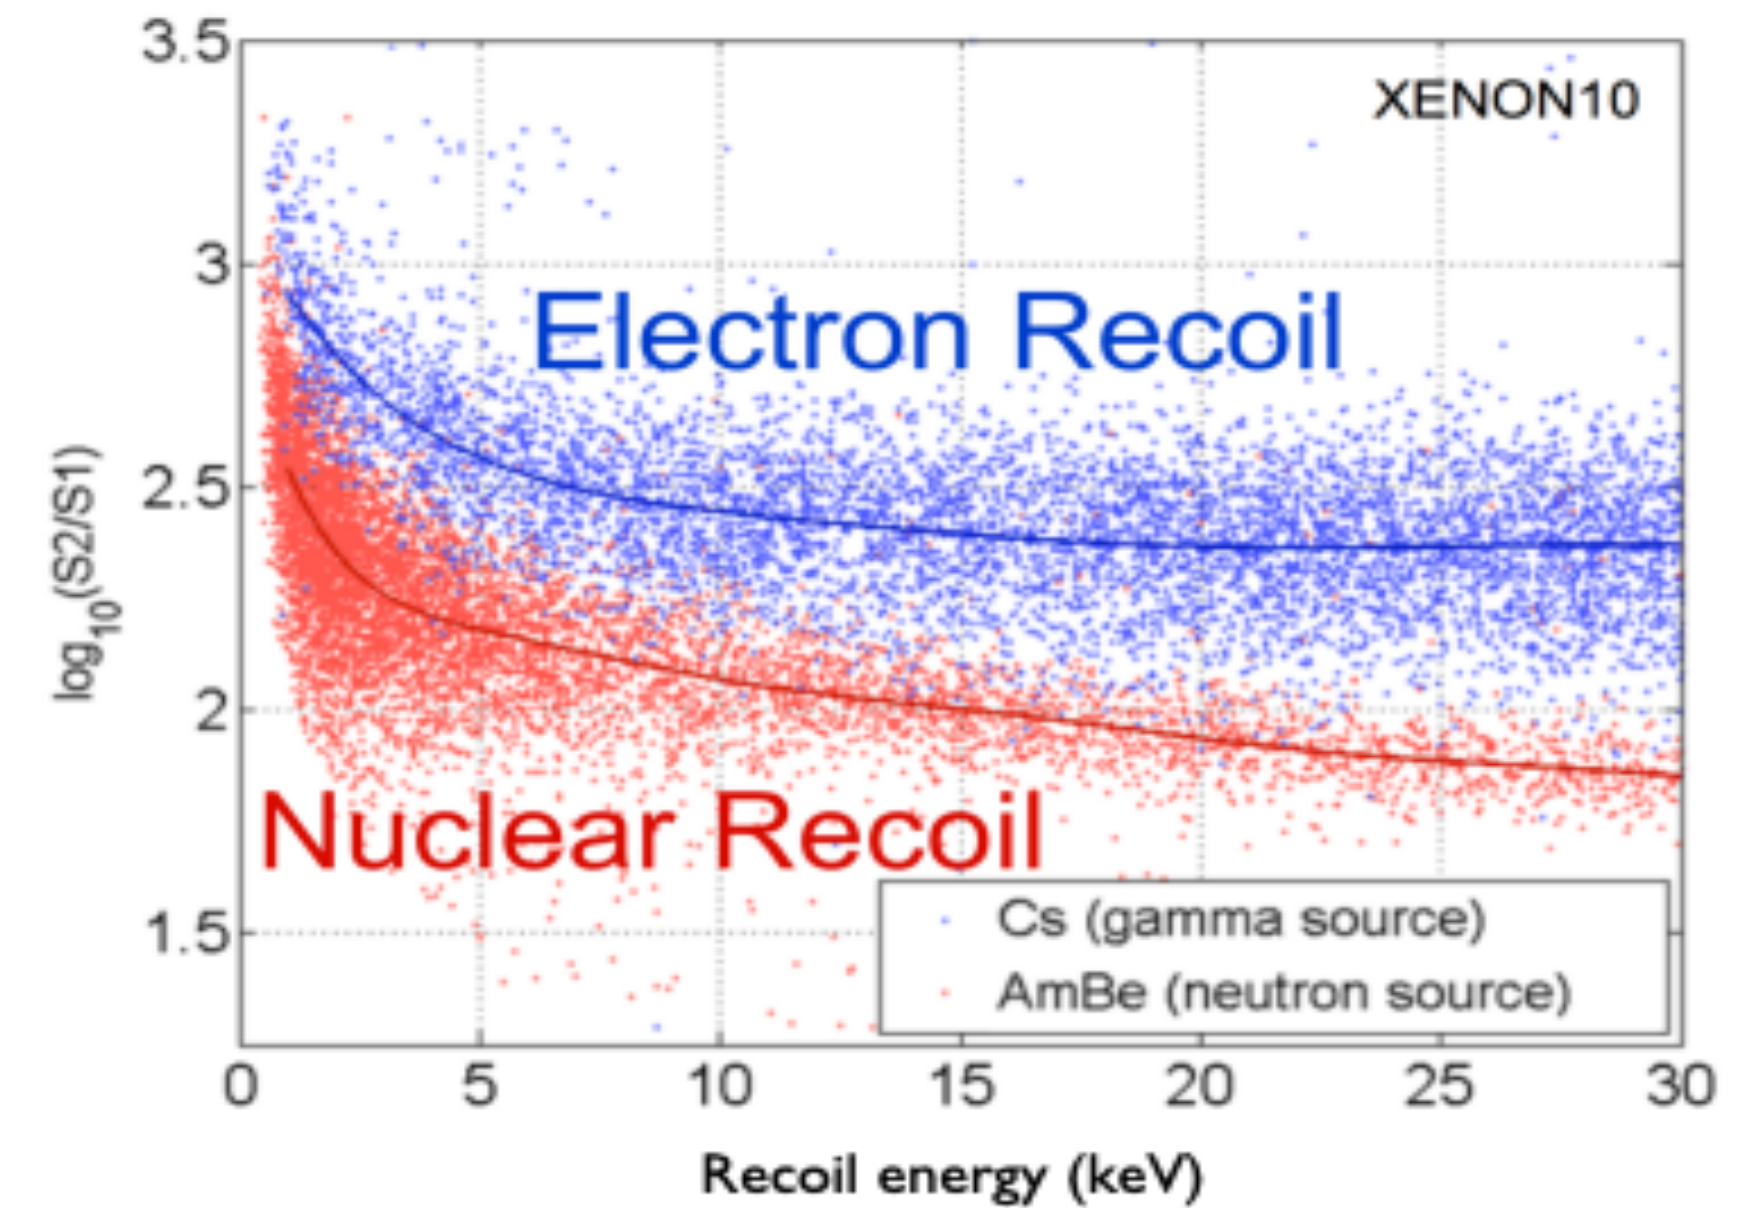

Nuclear Recoil: signal-like

Low-background and good discrimination!
LXe ER Leakage suppression >99.9%

Recoiling Ar Nucleus

Recoiling Xe Nucleus

Outline

- Landscape of Particle Dark Matter Search
- Overview of LZ-ZEPLIN Detector
- First Results of LUX-ZEPLIN
- Future LZ, XLZD and Beyond

Where is LZ Detector?

- Located 4850 ft under Sanford Underground Research Facility (SURF) in South Dakota
- Former gold mine, now the underground lab
- 4300 m.w.e, 10^6 muon reduction

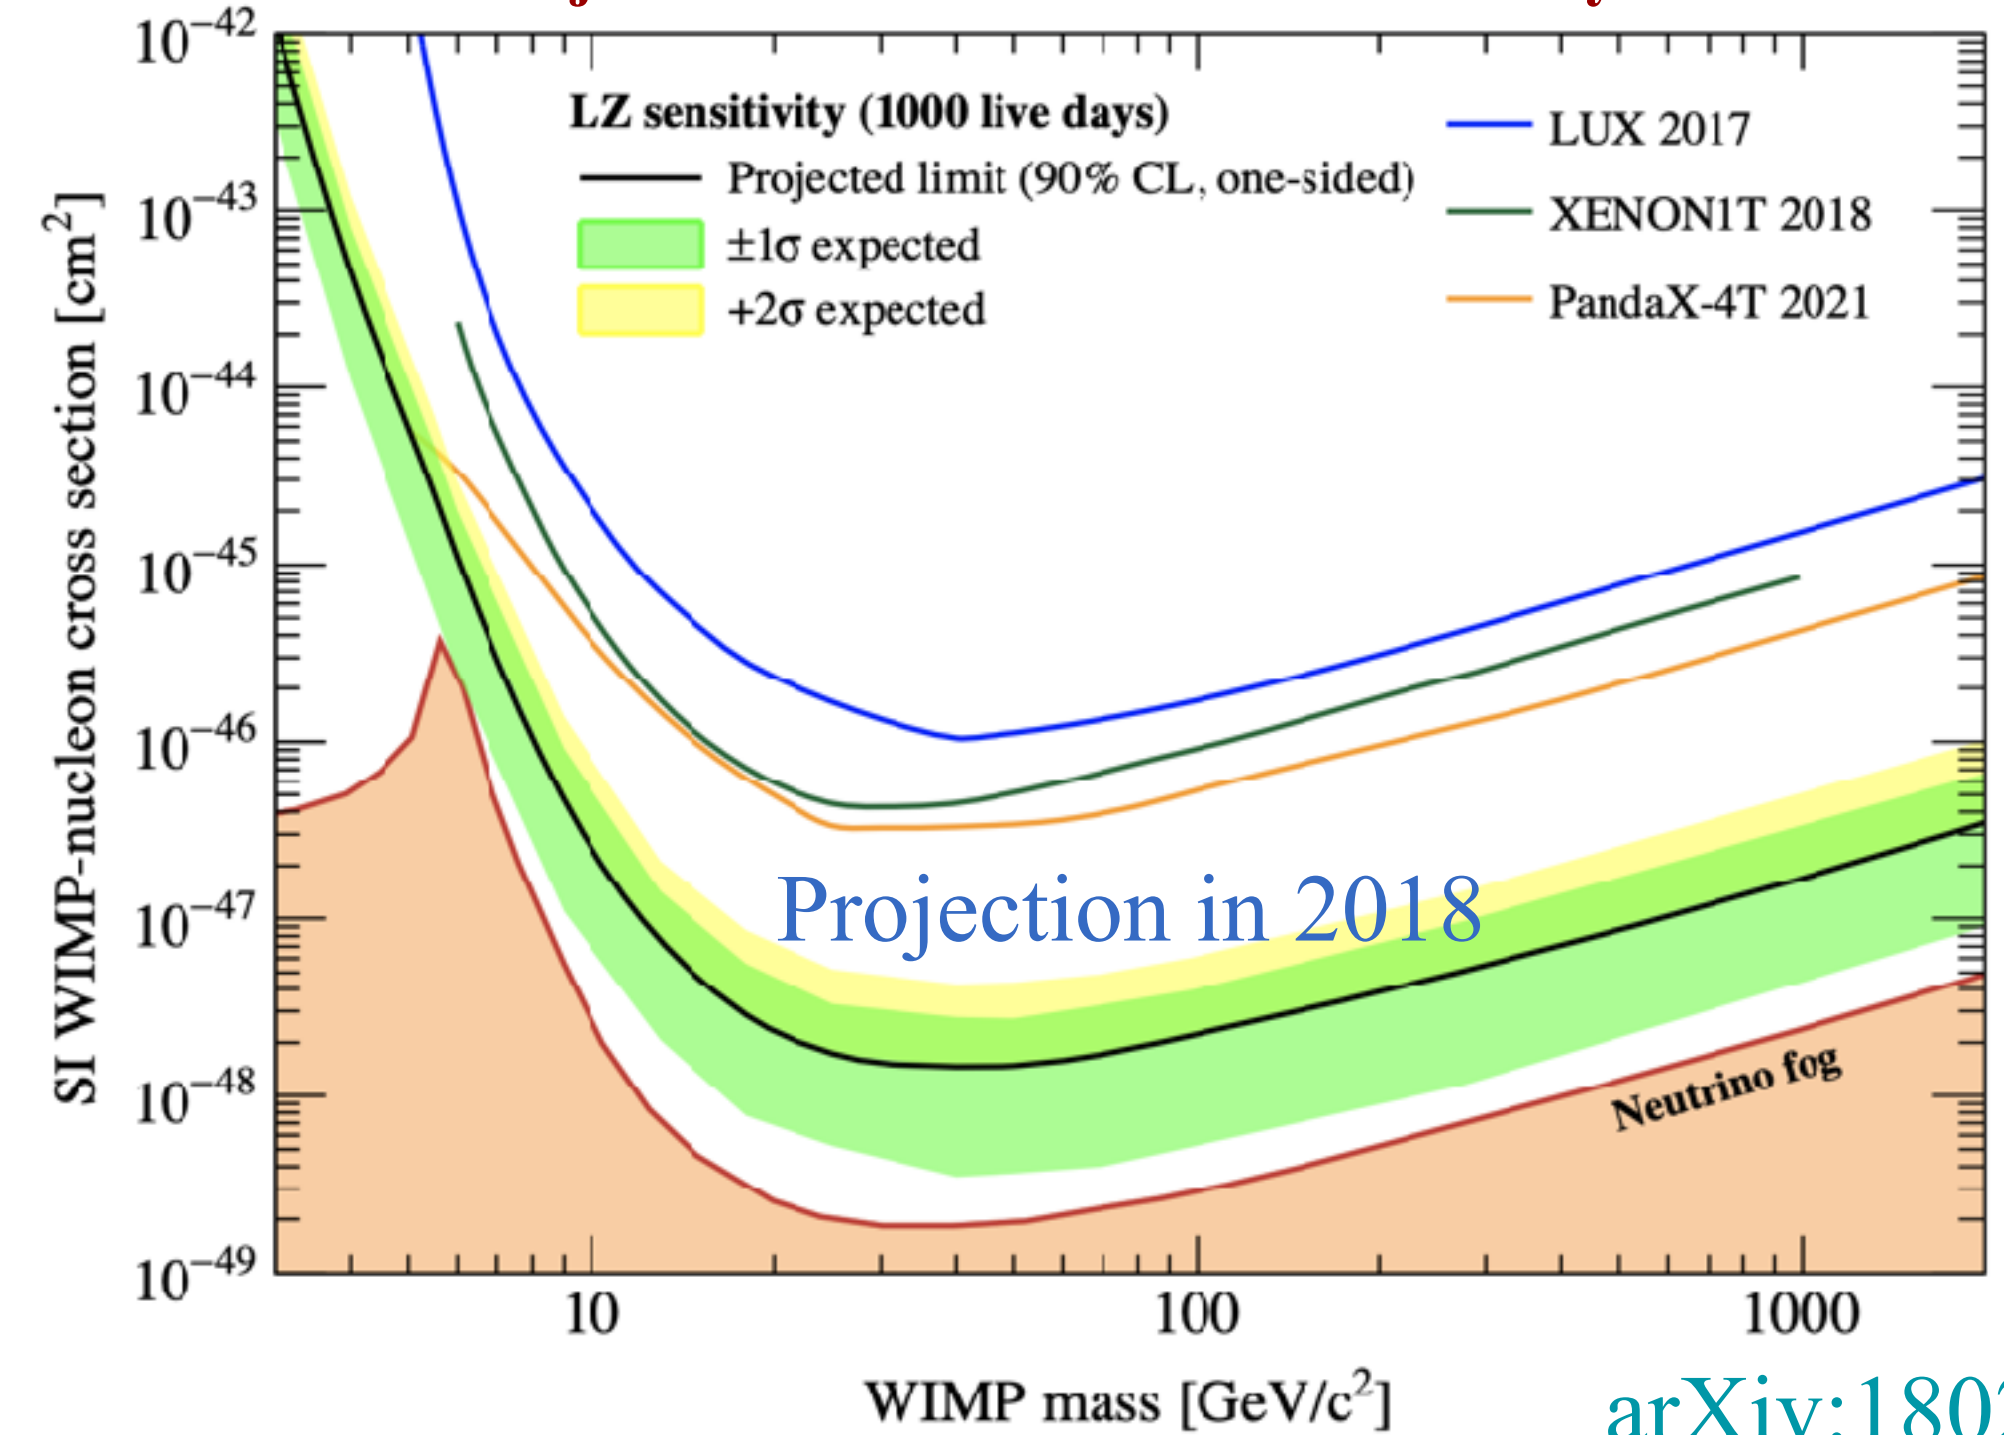

What is LZ trying to do?

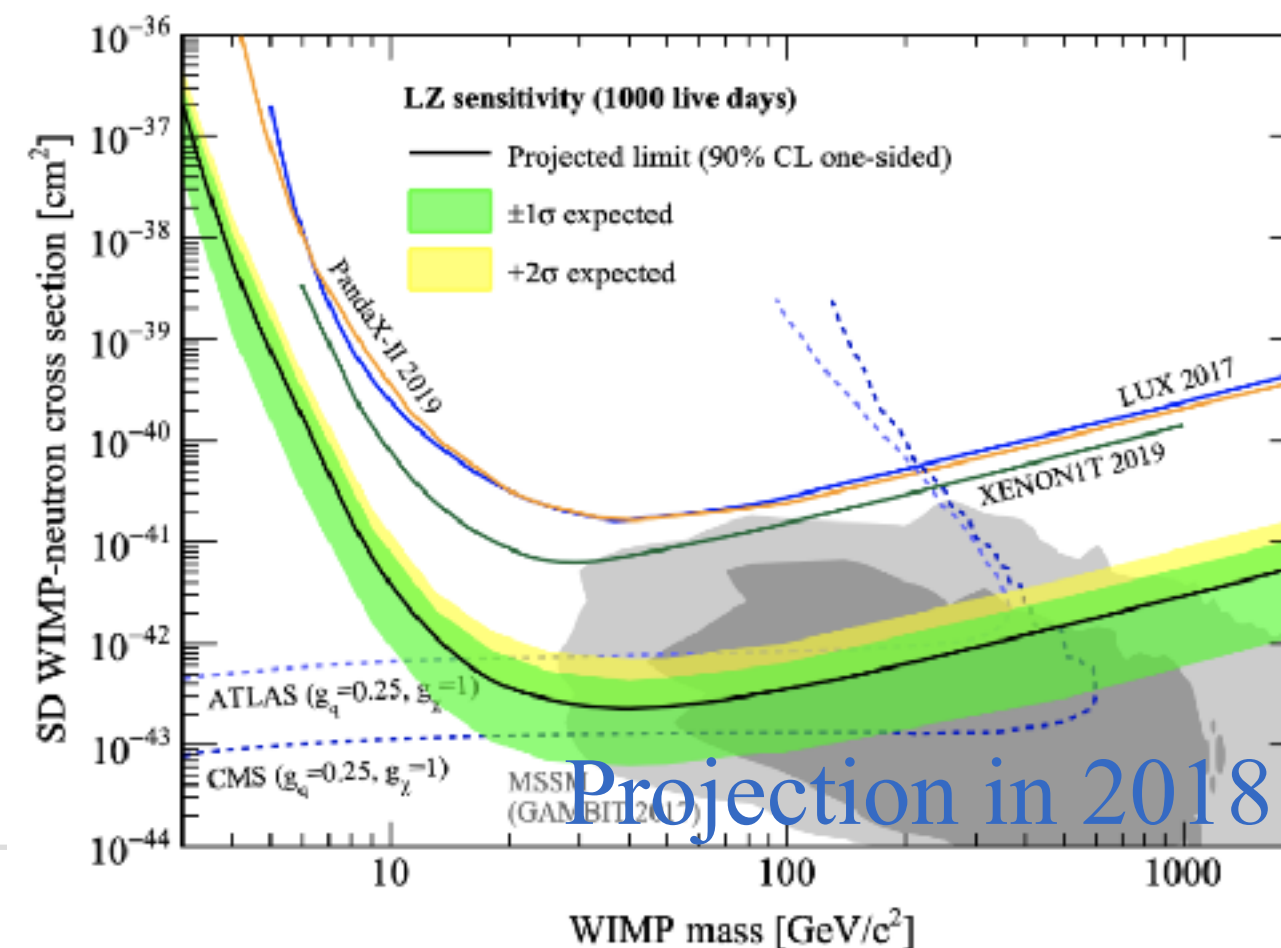

- LZ detector is multi-purpose (*Swiss-Army-Knife*)
- Projected (2018) to have world-leading DM Sensitivity
 - Full exposure: 15.3 tonne-year
 - SI WIMP-nucleon sensitivity: $1.4 \times 10^{-48} \text{ cm}^2$ @ 40 GeV
 - SD WIMP-neutron (proton) sensitivity: 2.7×10^{-43} (7.1×10^{-42}) cm^2 @ 40 GeV
 - *Sub-GeV* masses accessible via Migdal effect, S2-only search
- Search of Other DM Candidates:
 - ALPs, hidden photon, mirror DM, etc
- Non-DM Physics
 - Solar axions, supernova neutrinos
 - Neutrino magnetic moment
 - Search of $0\nu\beta\beta$
 - $2\nu\text{ECEC}$ on ^{124}Xe

Projected SI WIMP-nucleon sensitivity

[arXiv:1802.06039](https://arxiv.org/abs/1802.06039)

How is LZ detectors structured?

The LZ Detector

- Nested doll structure (from center out):
 - Ultra-low background dual-phase TPC
 - 2-tonne of LXe skin as gamma veto
 - 17.3 t Gd-loaded LS as neutron+gamma veto
 - Water tank as muon veto

Construction Timeline

494 Hamamatsu R11410- 22 in LZ

Me Looking Tired

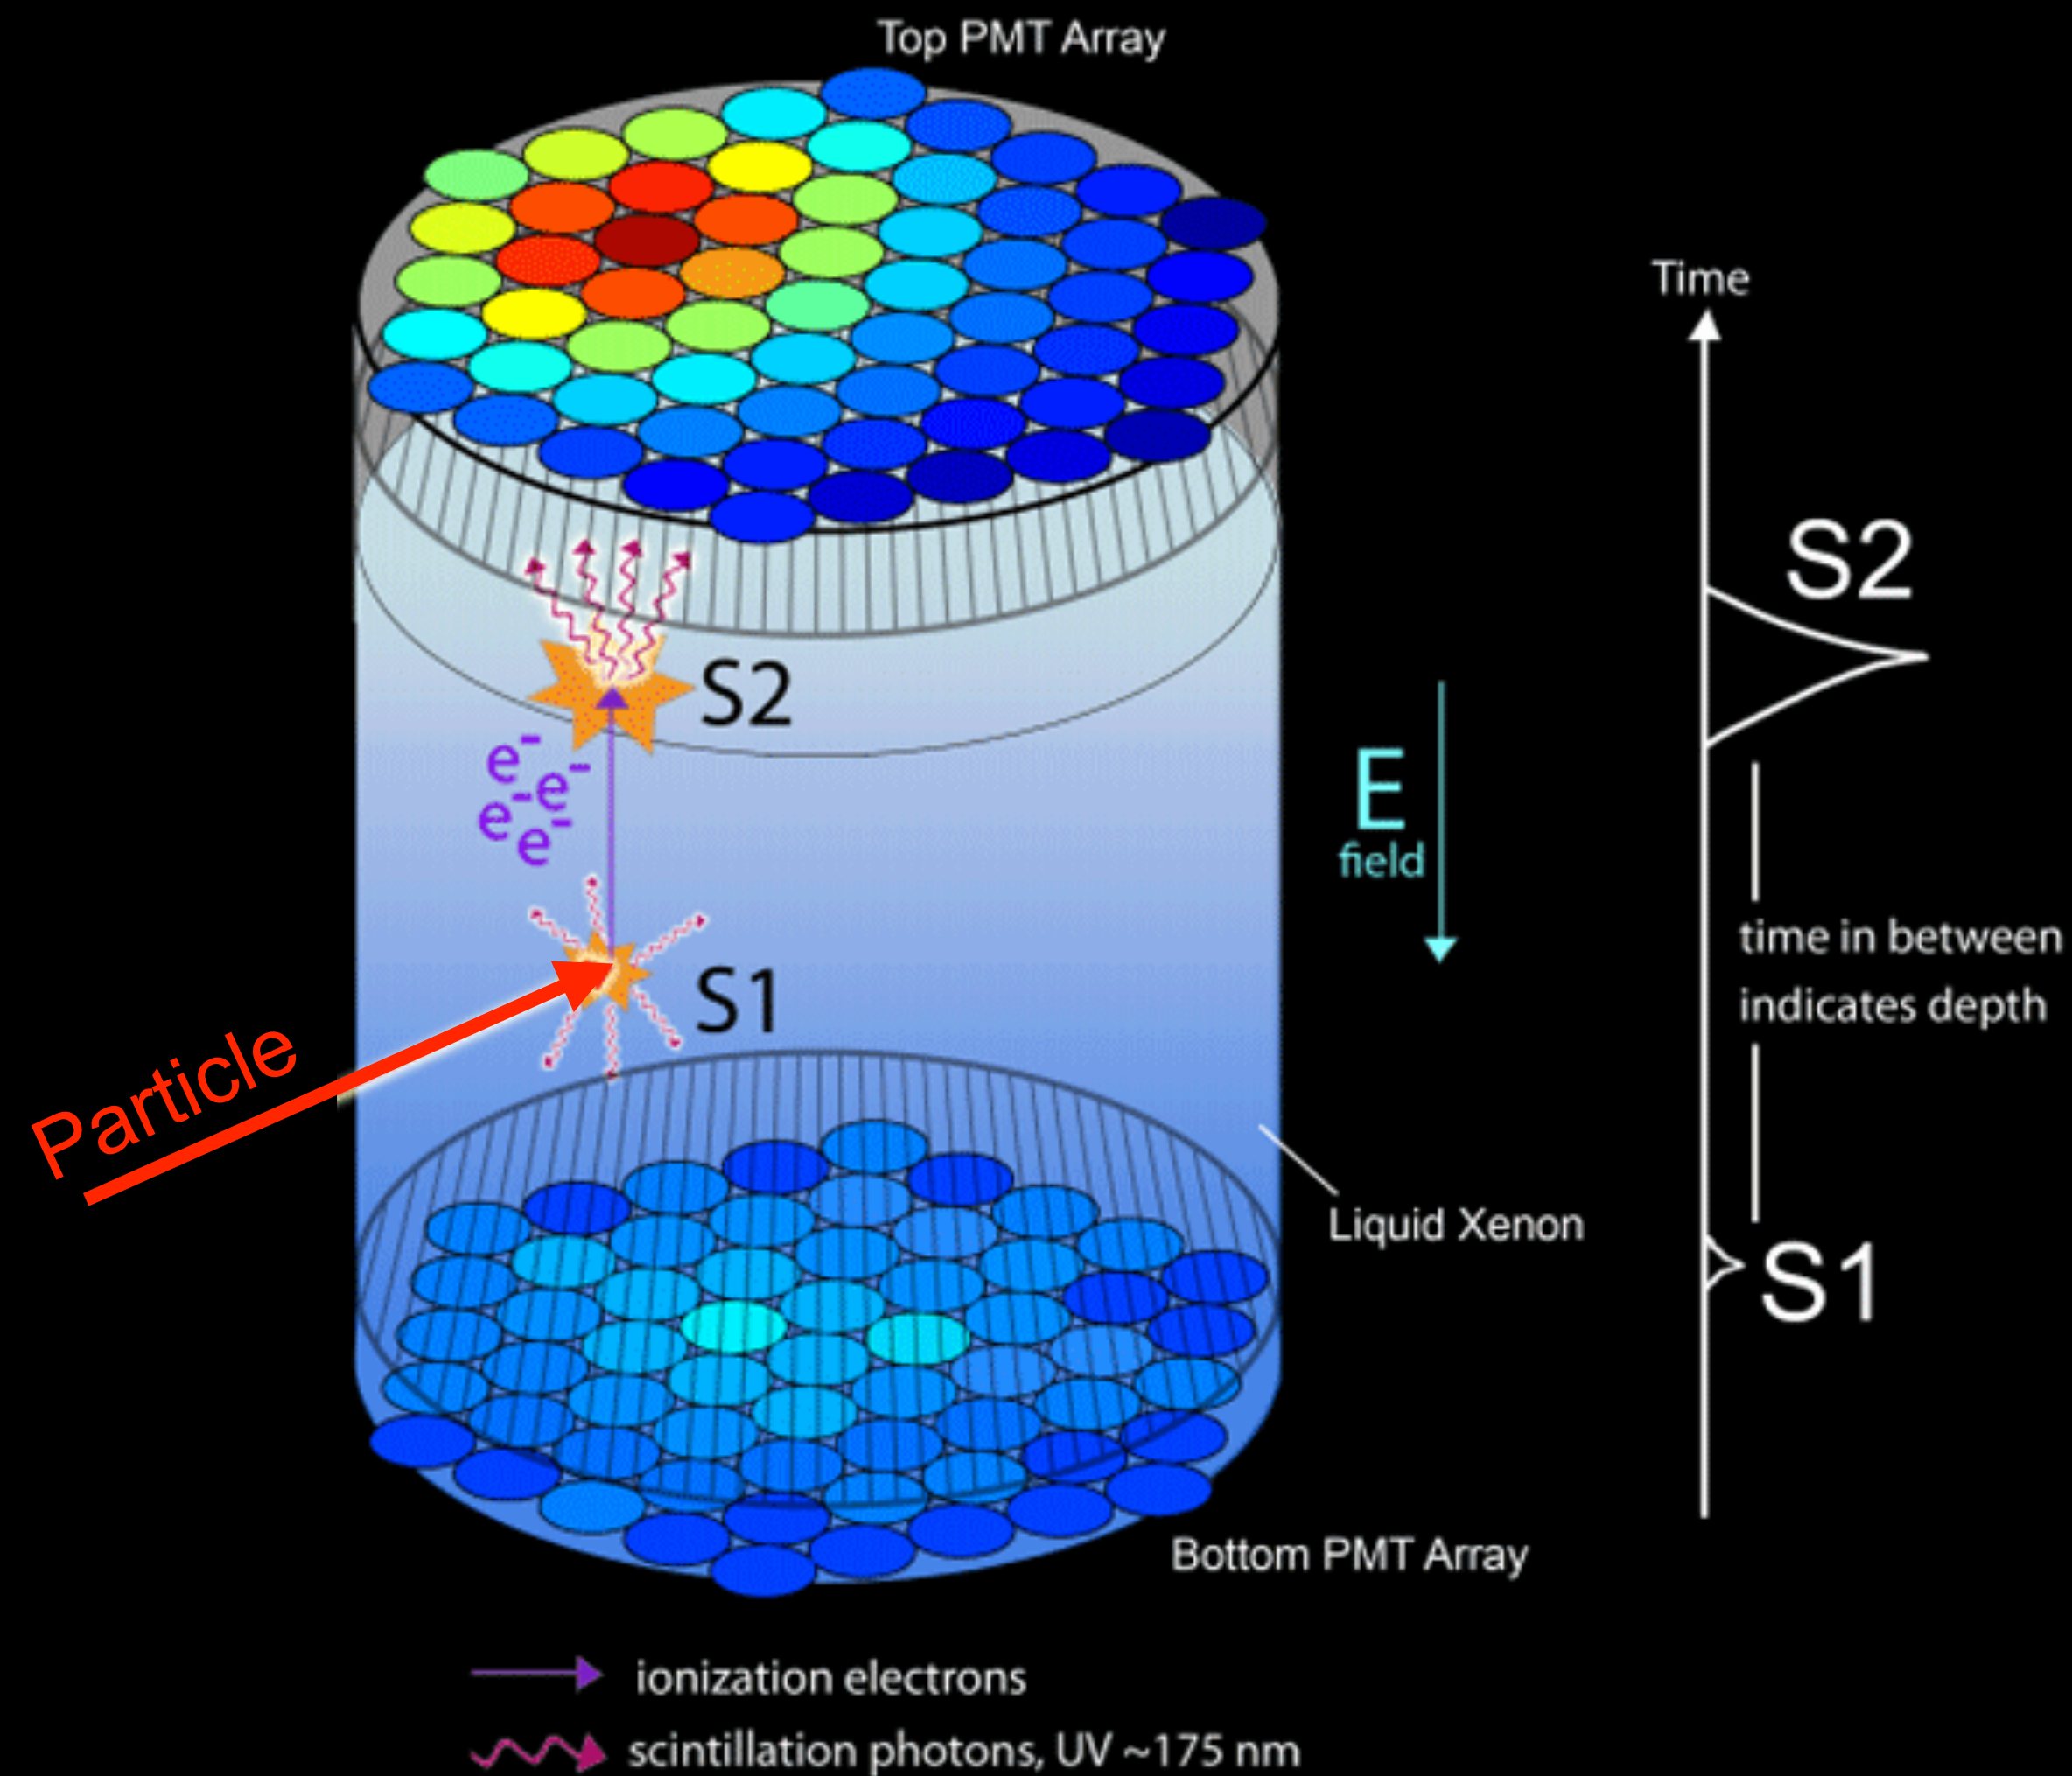

Transported to SURF in a customized
enclosure system

Assembled in Brown's clean room

How does liquid xenon TPC work?

Principle of a TPC

- Prompt primary scintillation light at interaction site → **S1**
- Ionization electrons are drifted to gas pocket where it produces light via electroluminescence → **S2**
- Drift time → **z position** at O(mm) precision.
- S2 channel pattern → **(x,y) positions** at O(cm) precision
- S2/S1 ratio → **Background discrimination:**
 - S2/S1 ratio depends on dE/dx
 - ER produces relatively more charge than NR

Non-relativistic elastic scattering at the keV scale => a single-scatter is point-like

How does the Veto system work?

Three Layers System:

1. A layer of **LXe skin** in the TPC inner cryostat, monitor by separated PMTs
 - a. Projected tagging γ -rays: **>70%**
2. Acyclic vessels surrounding TPC cryostat
 - a. Gd (0.1% doped) loaded LS (Linear Alkyl Benzene) [**manufactured at BNL (M. Yeh)**]
 - b. Neutron captured on H: 2.2 MeV
 - c. Neutron captured on Gd (4-5 γ -rays):
 - i. $n + {}^{155}\text{Gd} \rightarrow {}^{156}\text{Gd} + 8.5 \text{ MeV}$ (18%)
 - ii. $n + {}^{157}\text{Gd} \rightarrow {}^{158}\text{Gd} + 7.9 \text{ MeV}$ (82%)
 - d. Neutron veto: **(88.5 \pm 0.7)% efficiency with 5% acceptance loss**
3. Water Tank as a passive shielding

Acyclic Vessels Inside the Water Tank

Acrylic vessel, PMTs, and Tyvek Wrapping

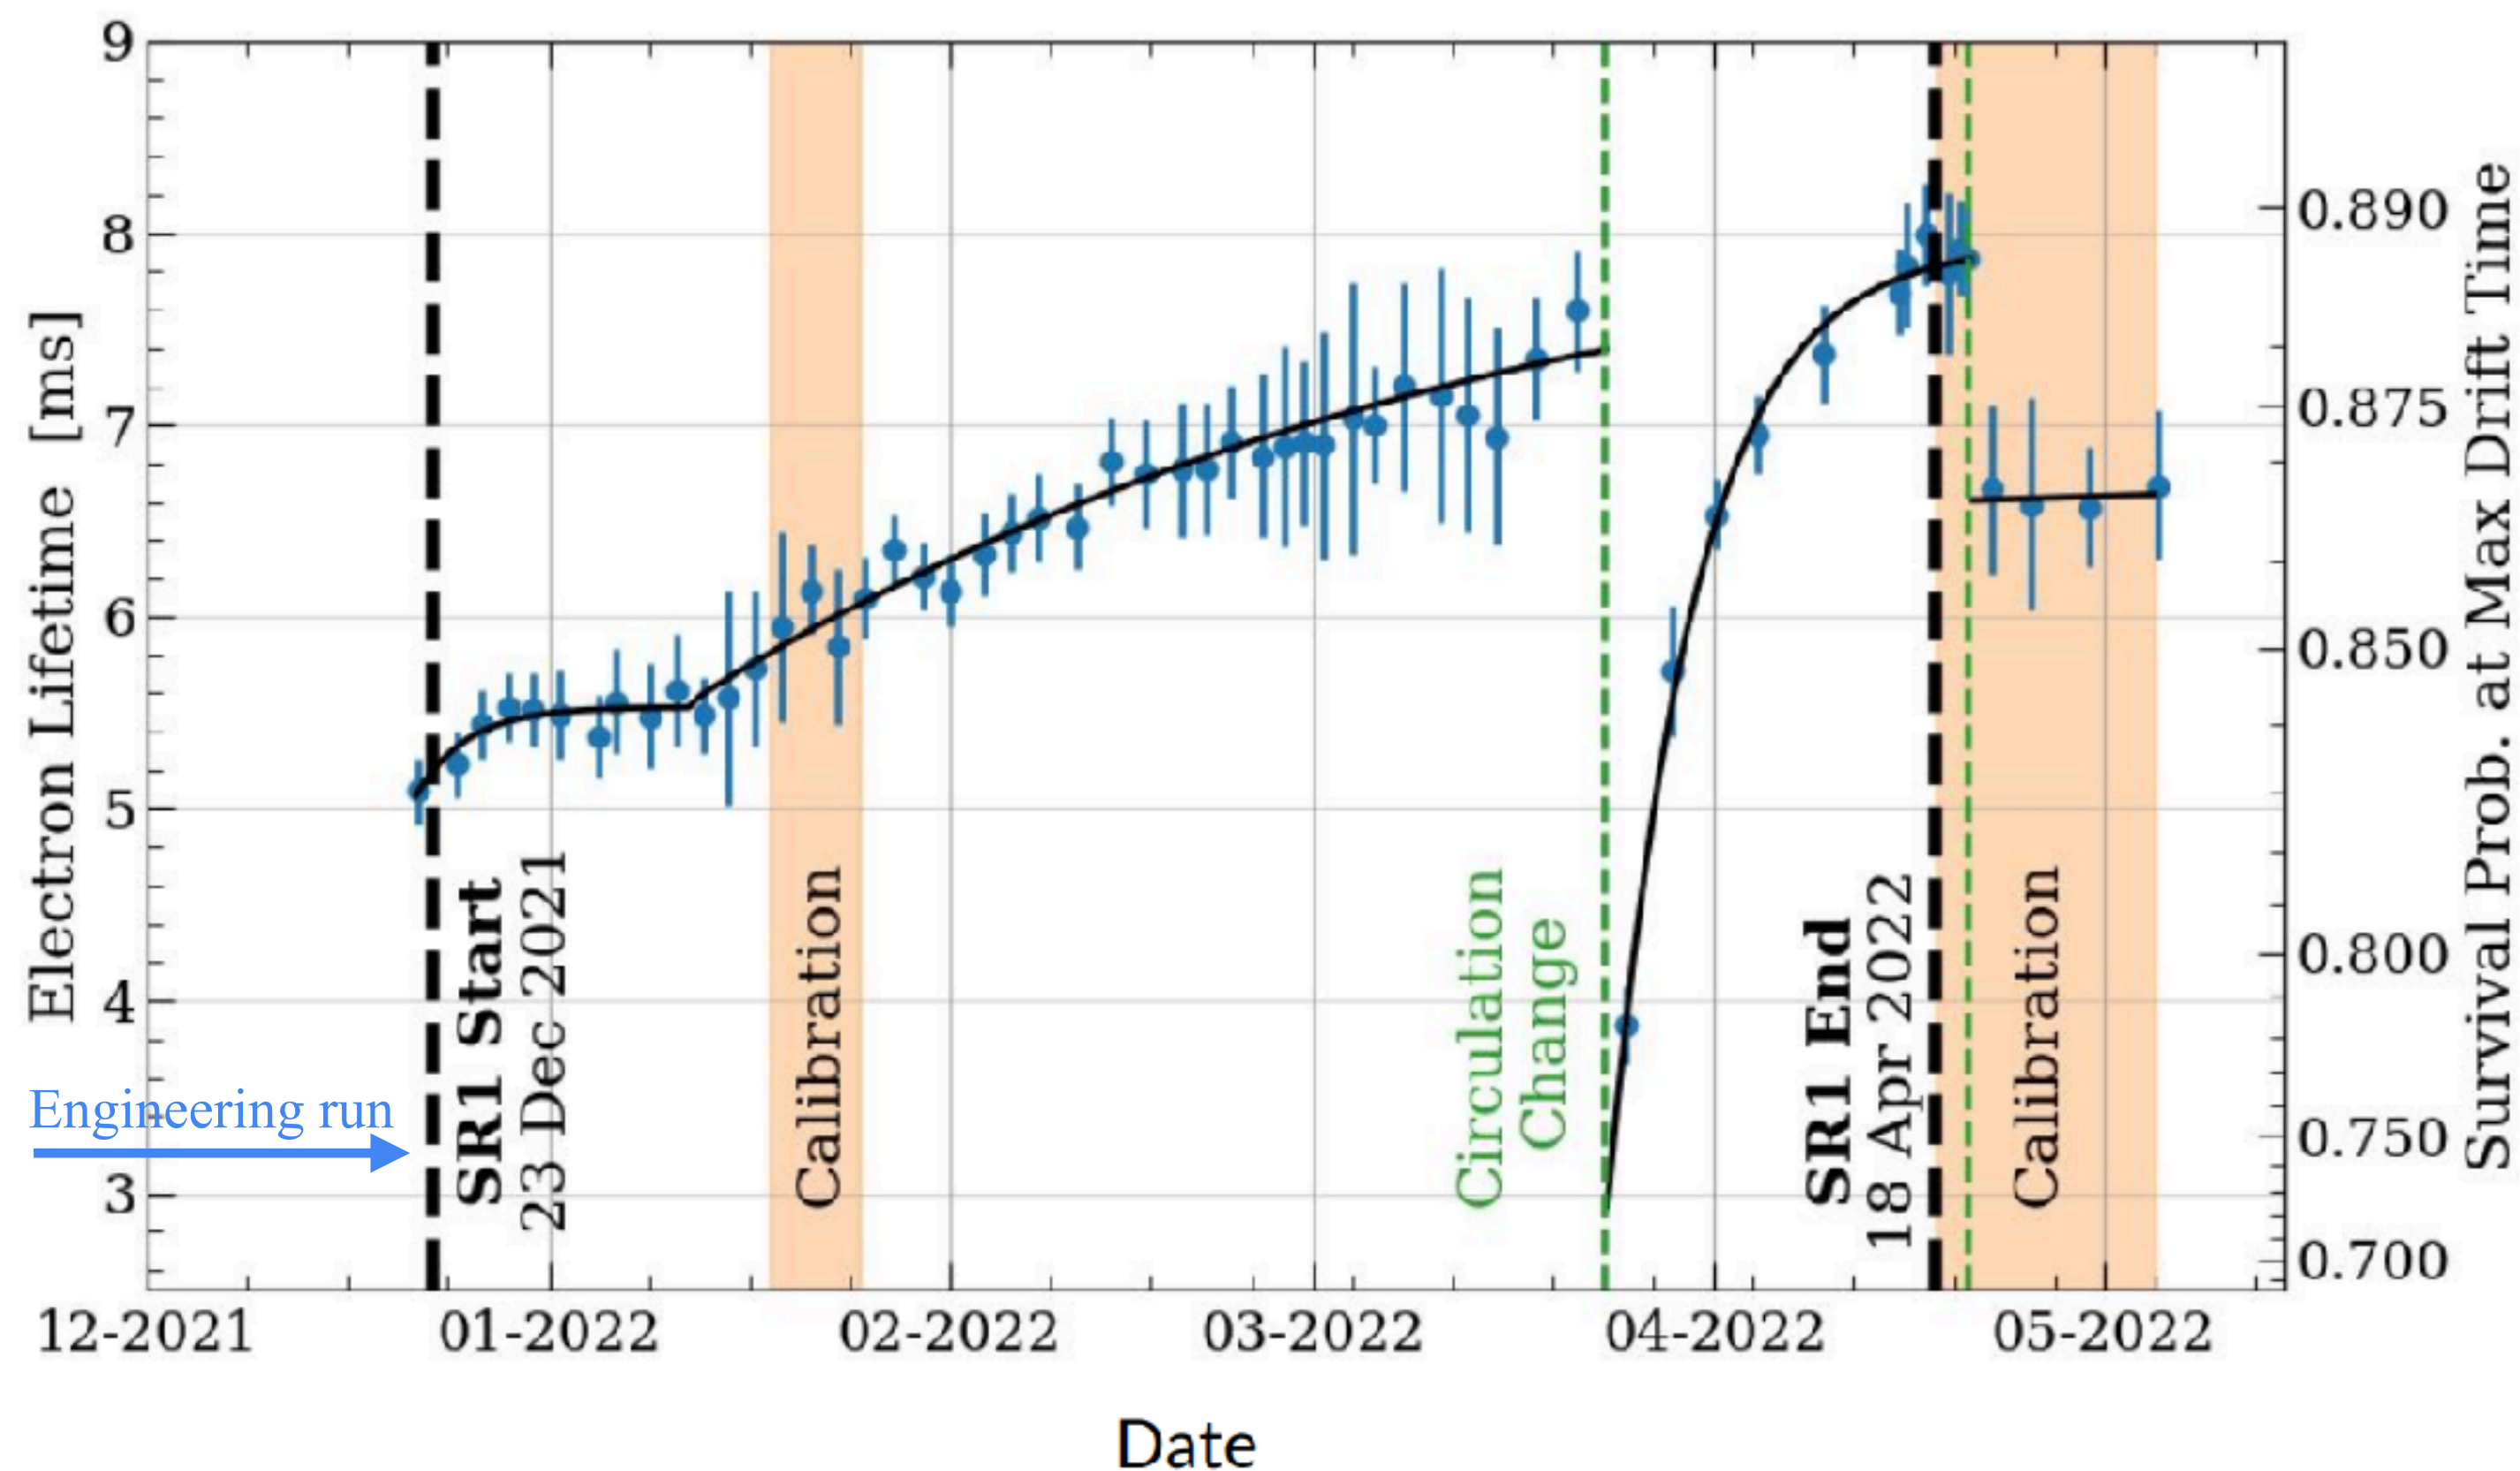

Outline

- Landscape of Particle Dark Matter Search
- Overview of LZ-ZEPLIN Detector
- **First Results of LUX-ZEPLIN**
- Future LZ, XLZD and Beyond

SR1 Timeline

- Begin on Dec 23, 21 end on May 12, 22
- 60 live days of for WIMP search
- Stable operation throughout the run:
 - Drift field: **193 V/cm**
 - Extraction field: **7.3 kV/cm**
 - Electron drift lifetime is steadily improved
 - **>97%** PMTs operational throughout the run
- Two main Goals of SR1:
 - Demonstrate the capability of the detector
 - Competitive SI-WIMP sensitivity

Calibration (but first let's review the notation)

Reminders:

S1: Prompt primary scintillation light at interaction site.

S2: Electroluminescence produced in the gas pocket; S2 is proportional to the ionization electrons.

Nuclear Recoil (NR): signal-like

Electronic Recoil (ER): background-like

Subscript “c” means S1, S2 are corrected to the TPC’s geometric center

Unit “phd” stands for photon detected

keV_{ee} : energy unit for ER
 keV_{nr} : energy unit for NR

Calibration

ER Sources:

- **Tritium: continuum beta (end-point: 18.6 keV)**
- Monoenergetic ^{83m}Kr (32.1keV, 9.4 keV)
- Monoenergetic ^{131m}Xe (164 keV)
- Various Xe activation lines

NR Sources:

- **Deuterium-deuterium (DD) triggered 2.45 MeV neutron**
- AmLi: continuous, isotropic
- Alphas peaks

Calibrated detector parameters:

- Light collection efficiency (g1): **0.114 ± 0.002 phd/photon**
- Charge gain (g2): **47.1 ± 1.1 phd/electron**
- **>99.9%** rejection of ERs below the NR median
- Single electron size: 58.5
- Max drift time: 951 μs

The response of TPC, skin, and OD are comprehensively calibrated!

Direct WIMP search at its heart is a **process by elimination**

1. Data Selection (final live-time: 60 ± 1 d):
2. Event Selection
 - A. WIMP signature cut
 - B. Background rejection cut
3. Profile Likelihood Ratio (PLR)

- No blinding in signal region or salting
- All analysis cuts were developed and optimized using calibration and sideband selection

All single scatters before ANY other cuts

1. Data Selection

Elevated activities due to spurious instrumental effects

1. Data Selection (final live-time: 60 ± 1 d):

- Exclude time period of elevated activities (7% loss).
- Exclude DAQ deadtime (3% loss)
- **Hold-off after large S2s (30% loss)**
- Hold-off after cosmic muon

The grey regions are the hold-off time after large S2s

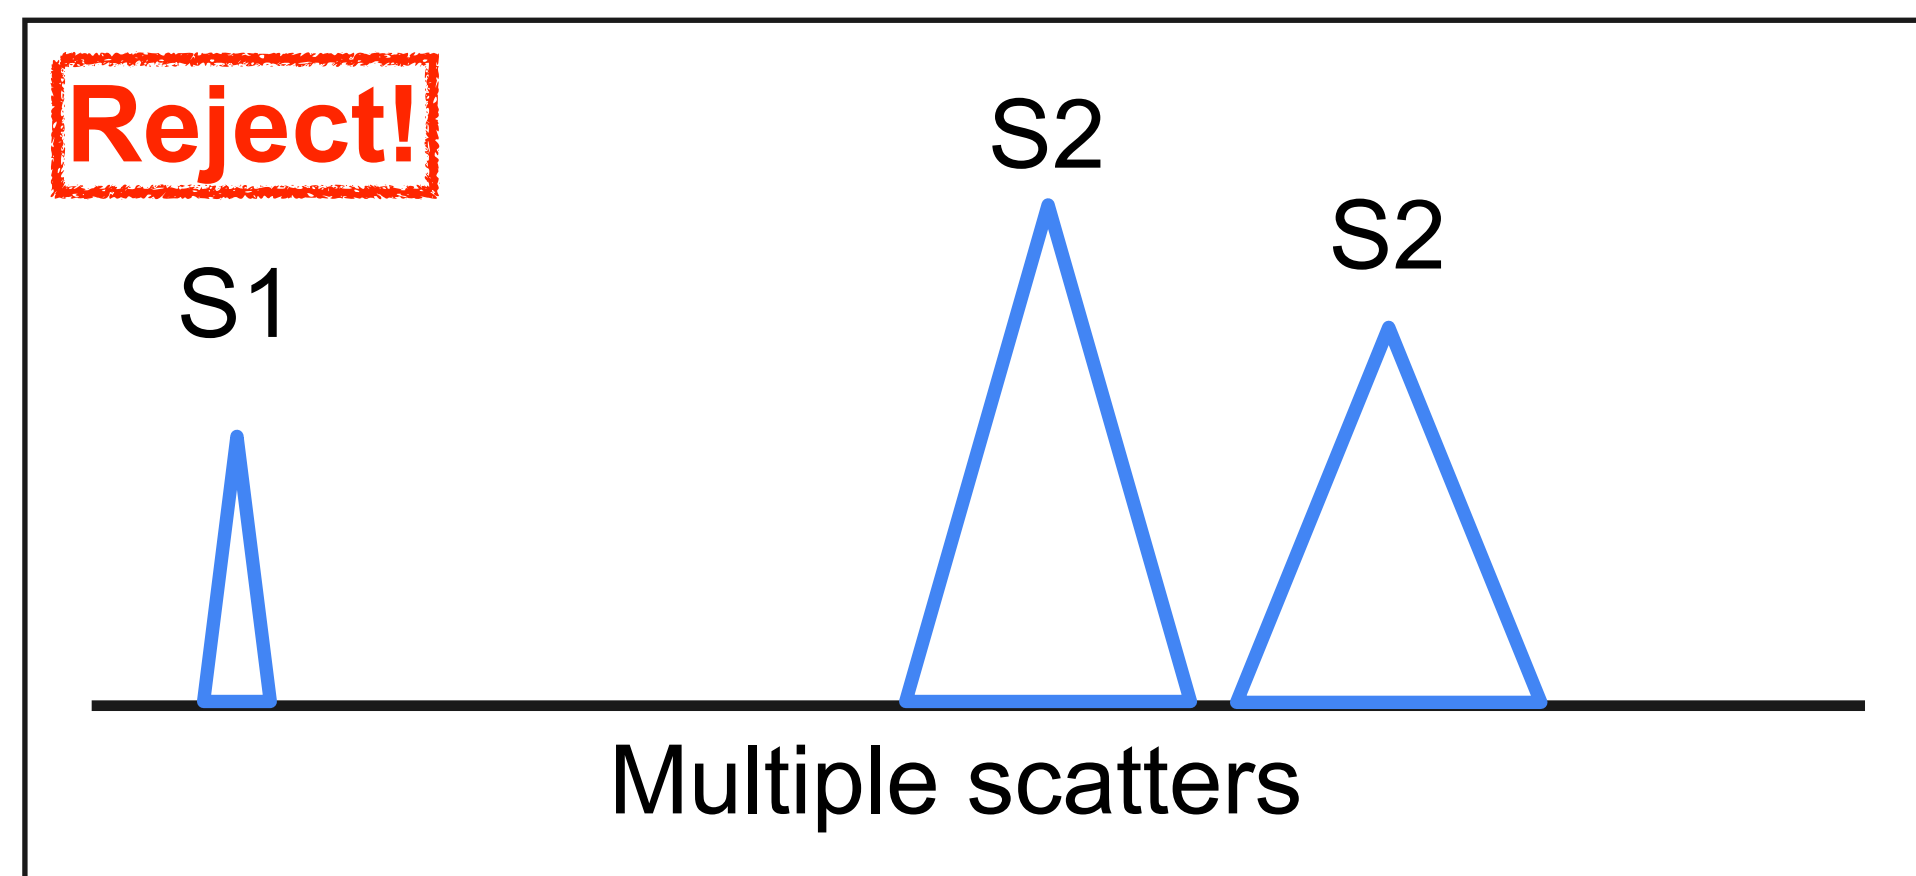

2. Event Selection

A. WIMP Selection

- Single-scatter without any OD coincidence
- Within the Region of Interest (ROI)

B. Background rejection cuts

Background Model

Accidental Coincidence (instrumental)

- An Isolated S1 piled-up with an isolated S2

Solar ν e-scattering:

- $pp + 7\text{Be} + 13\text{N}$

Dissolved e-captures:

- ^{37}Ar
- ^{127}Xe
- ^{124}Xe (double e-capture)

Detector γ -emitters:

- ^{238}U chain
- ^{232}Th Chain
- ^{40}K
- ^{60}Co

Nuclear Recoil

- Solar 8B CE ν NS
- Radiogenic (α, n) neutron
- Spontaneous fission

Dissolved β -emitters:

- ^{214}Pb (^{222}Rn daughter)
- ^{212}Pb (^{220}Rn daughter)
- ^{85}Kr
- ^{136}Xe ($2\nu\beta\beta$)

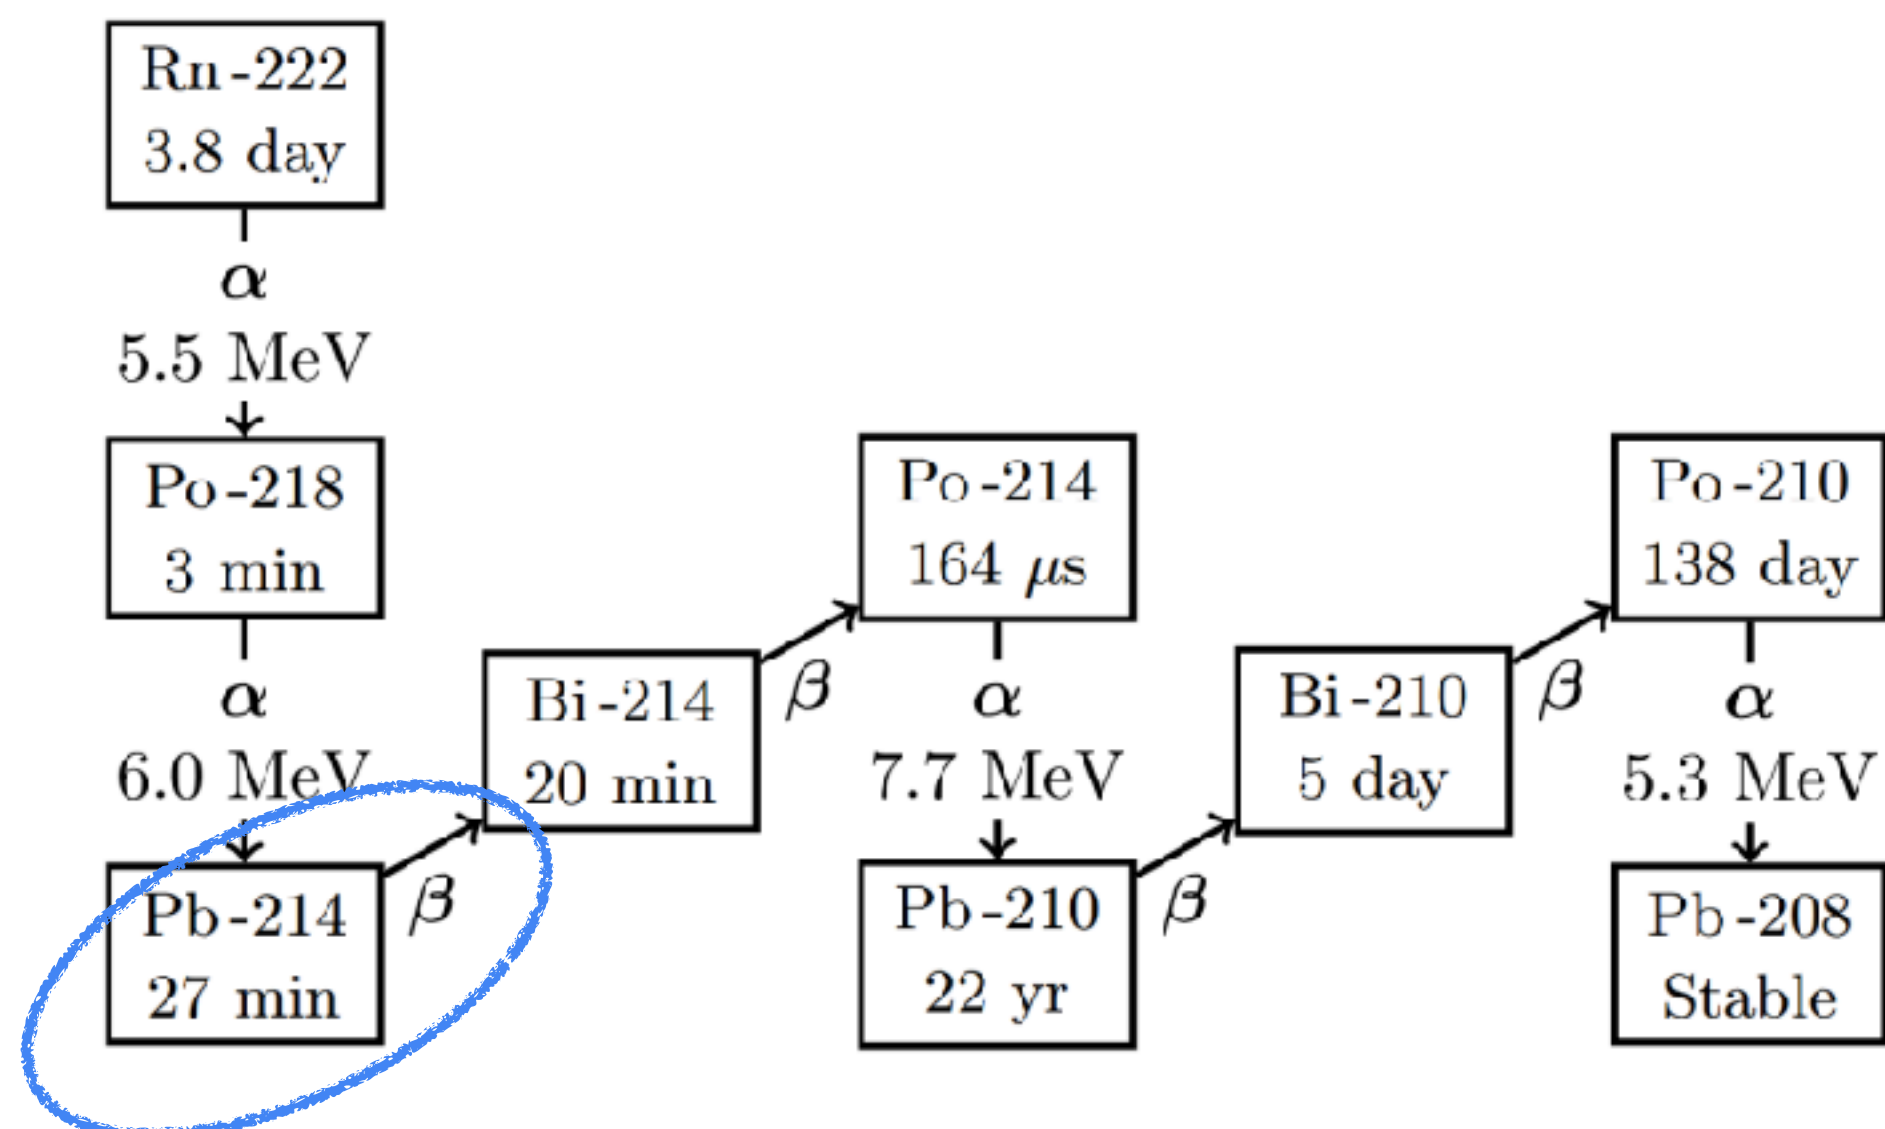

Radon as the main beta sources

Naked ^{214}Pb β -decays are the main source of background in the WIMP search

Constraint Rn-chain via α tagging

- MeV-scaled α are hard to miss
- ^{222}Rn activity within assay expectations

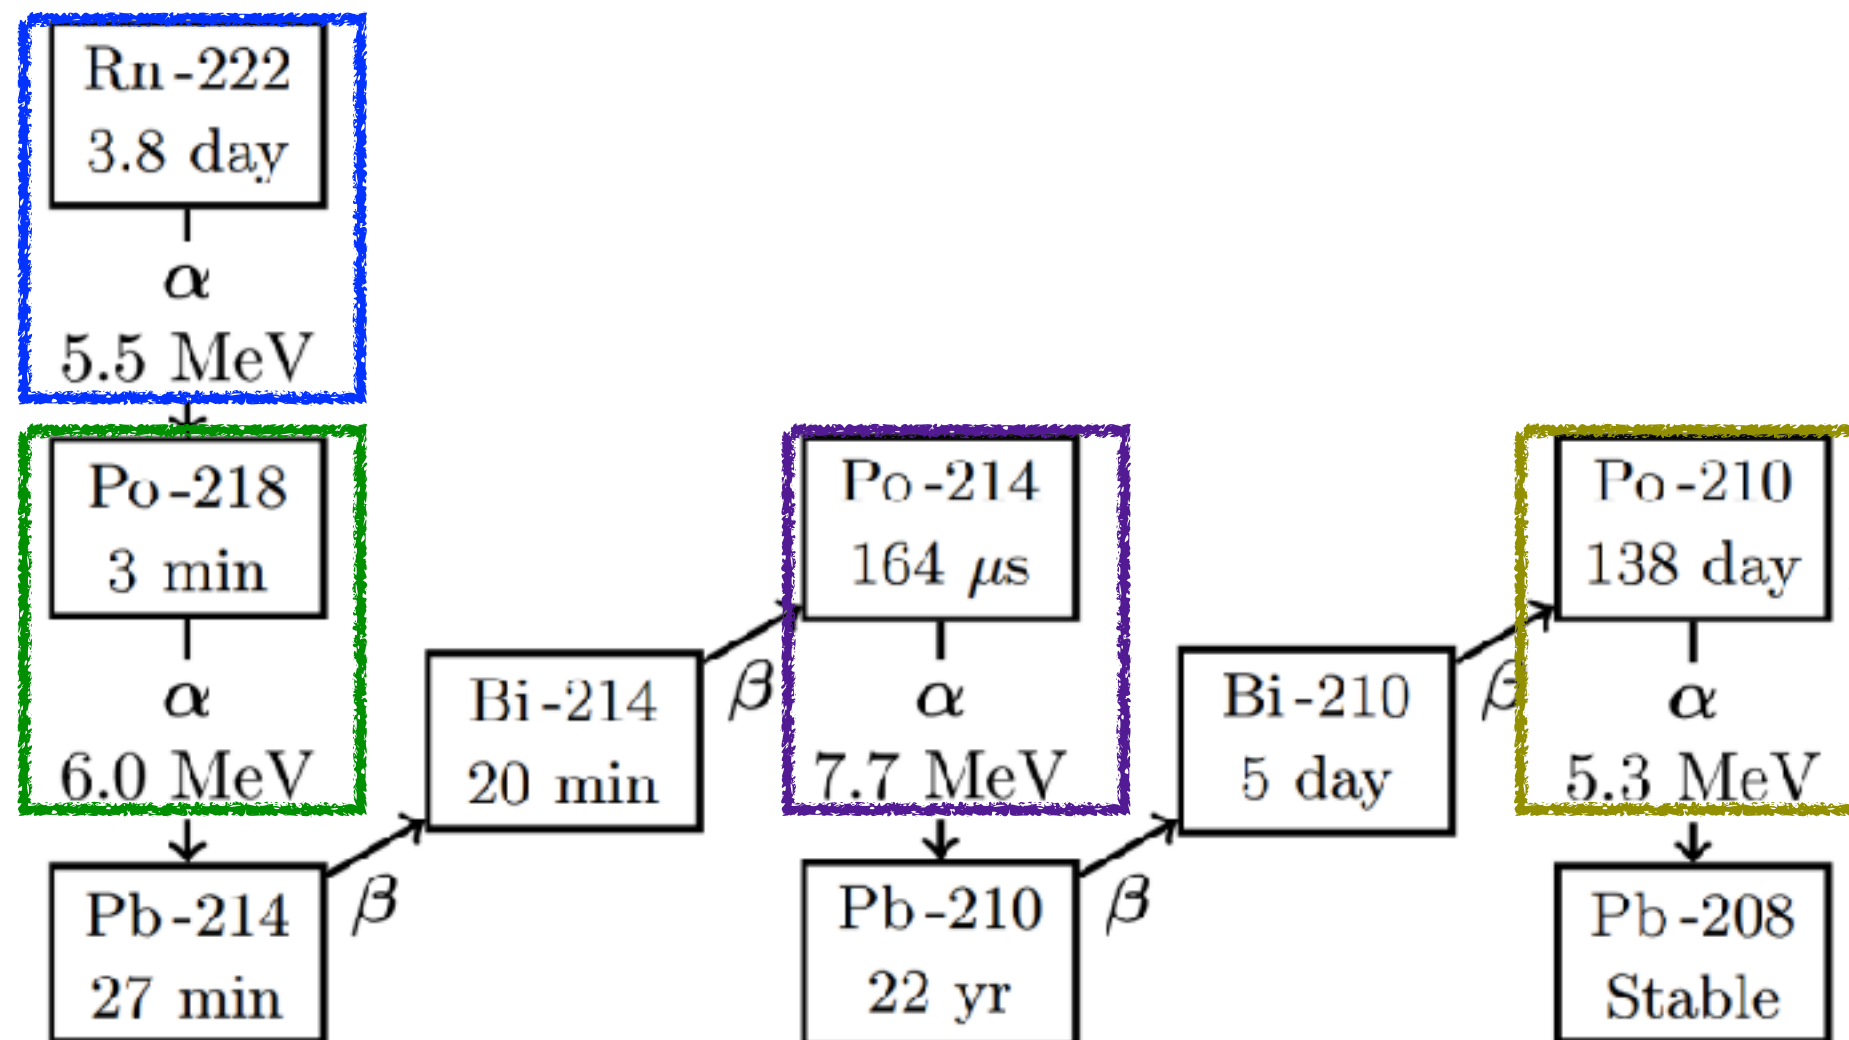

Radon as the main beta sources

Naked ^{214}Pb β -decays are the main source of background in the WIMP search

Constraint Rn-chain via α tagging

- MeV-scaled α are hard to miss
- ^{222}Rn activity within assay expectations

Rn220-chain:

- ^{212}Po
- ^{216}Po

Credit: [A. Al Musalhi \(IDM 2022\)](#)

Isotope (decay)	Activity [$\mu\text{Bq/kg}$]
^{222}Rn (alpha)	4.37 ± 0.31 (stat)
^{218}Po (alpha)	4.51 ± 0.32 (stat)
^{214}Pb (beta)	3.26 ± 0.13 (stat) ± 0.57 (sys)
^{214}Po (alpha)	2.56 ± 0.21 (stat)

Radon as the main beta sources

Naked ^{214}Pb β -decays are the main source of background in the WIMP search

Constraint via spectrum fit above WIMP energy ROI

- Various featured Xe activation peaks outside energy ROI
- ^{214}Pb constrained by baseline

Credit:

[A. Al Musalhi \(IDM 2022\)](#)

Electron-captured

^{37}Ar (2.8 keV, $t_{1/2}=35\text{d}$) dominates at low energy

Produced by cosmic spallation of natural xenon during the transport

- Activity calculated using delivery schedule
- Expected **~100 decays** of ^{37}Ar in SR1 with large uncertainty

Solar Neutrinos (small overall)

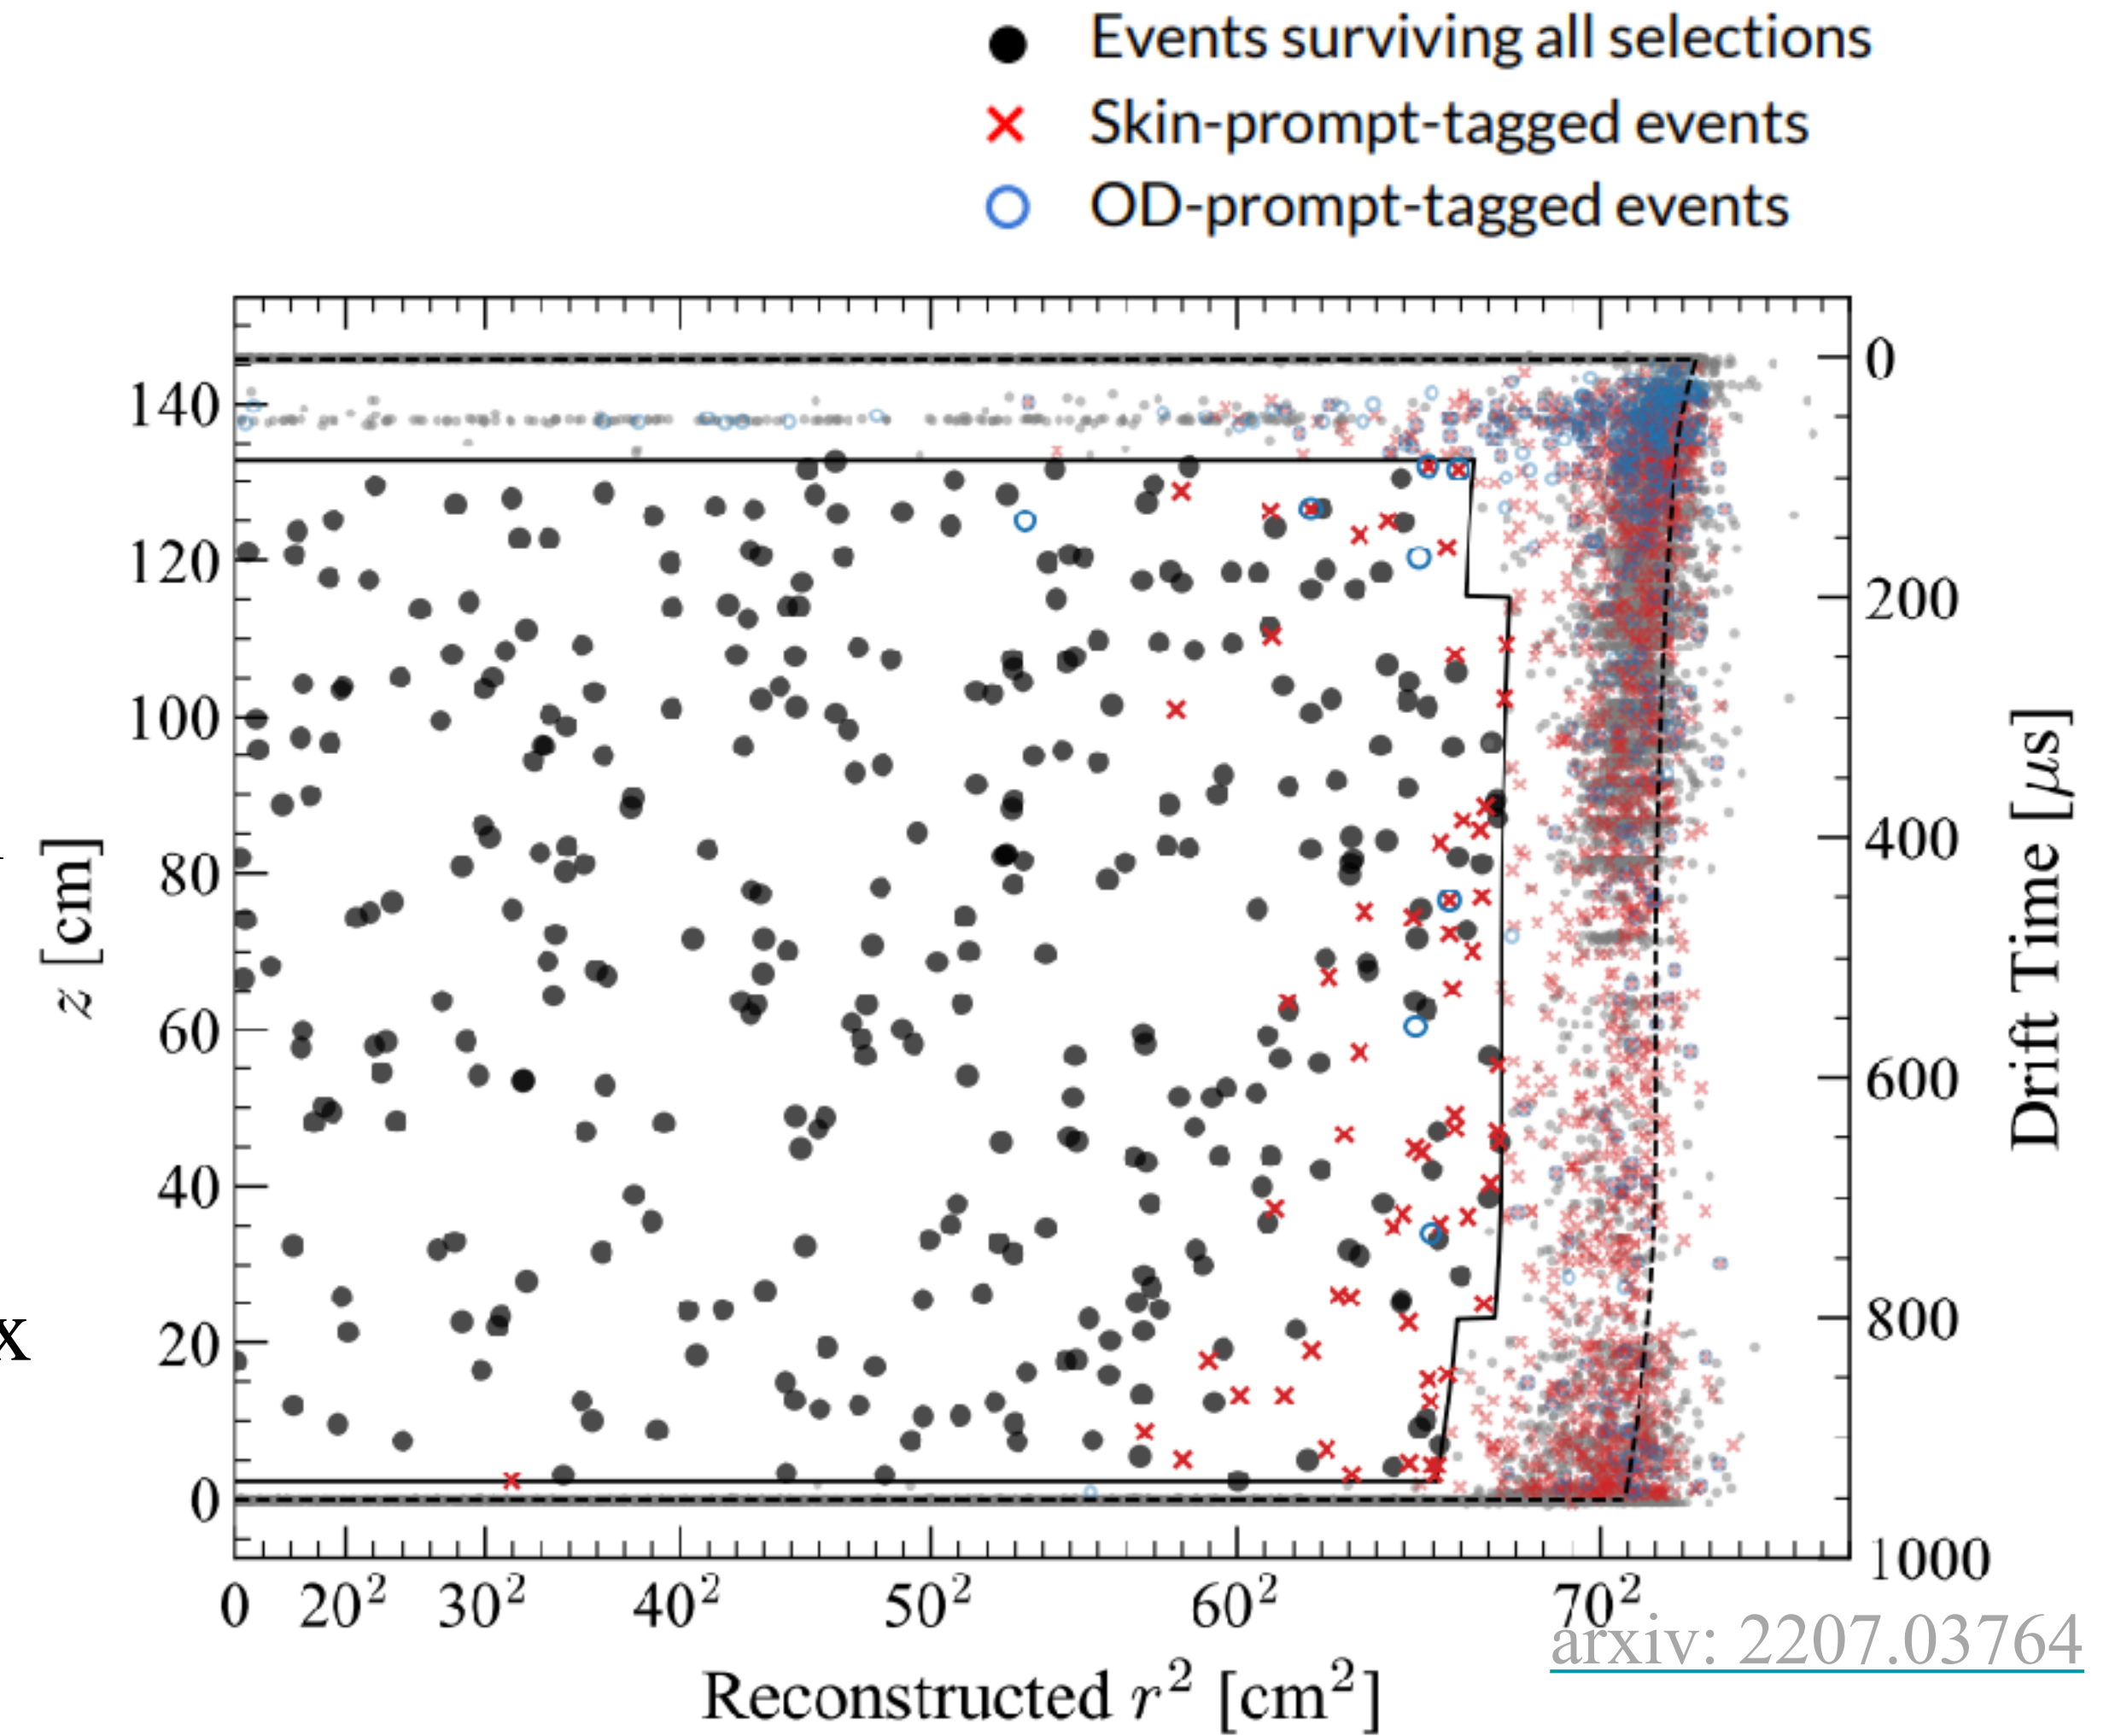

- Neutrino induced ER are mostly: pp, ⁷Be, CNO neutrinos (27.3 events)
- NR are mostly ⁸B CEvNS, suppressed by relatively high threshold (0.15 events)
 - S1c > 3phd & S1 coincidence ≥ 3-fold
 - S2 > 600 phd (electron > 10)

Fiducial Volume

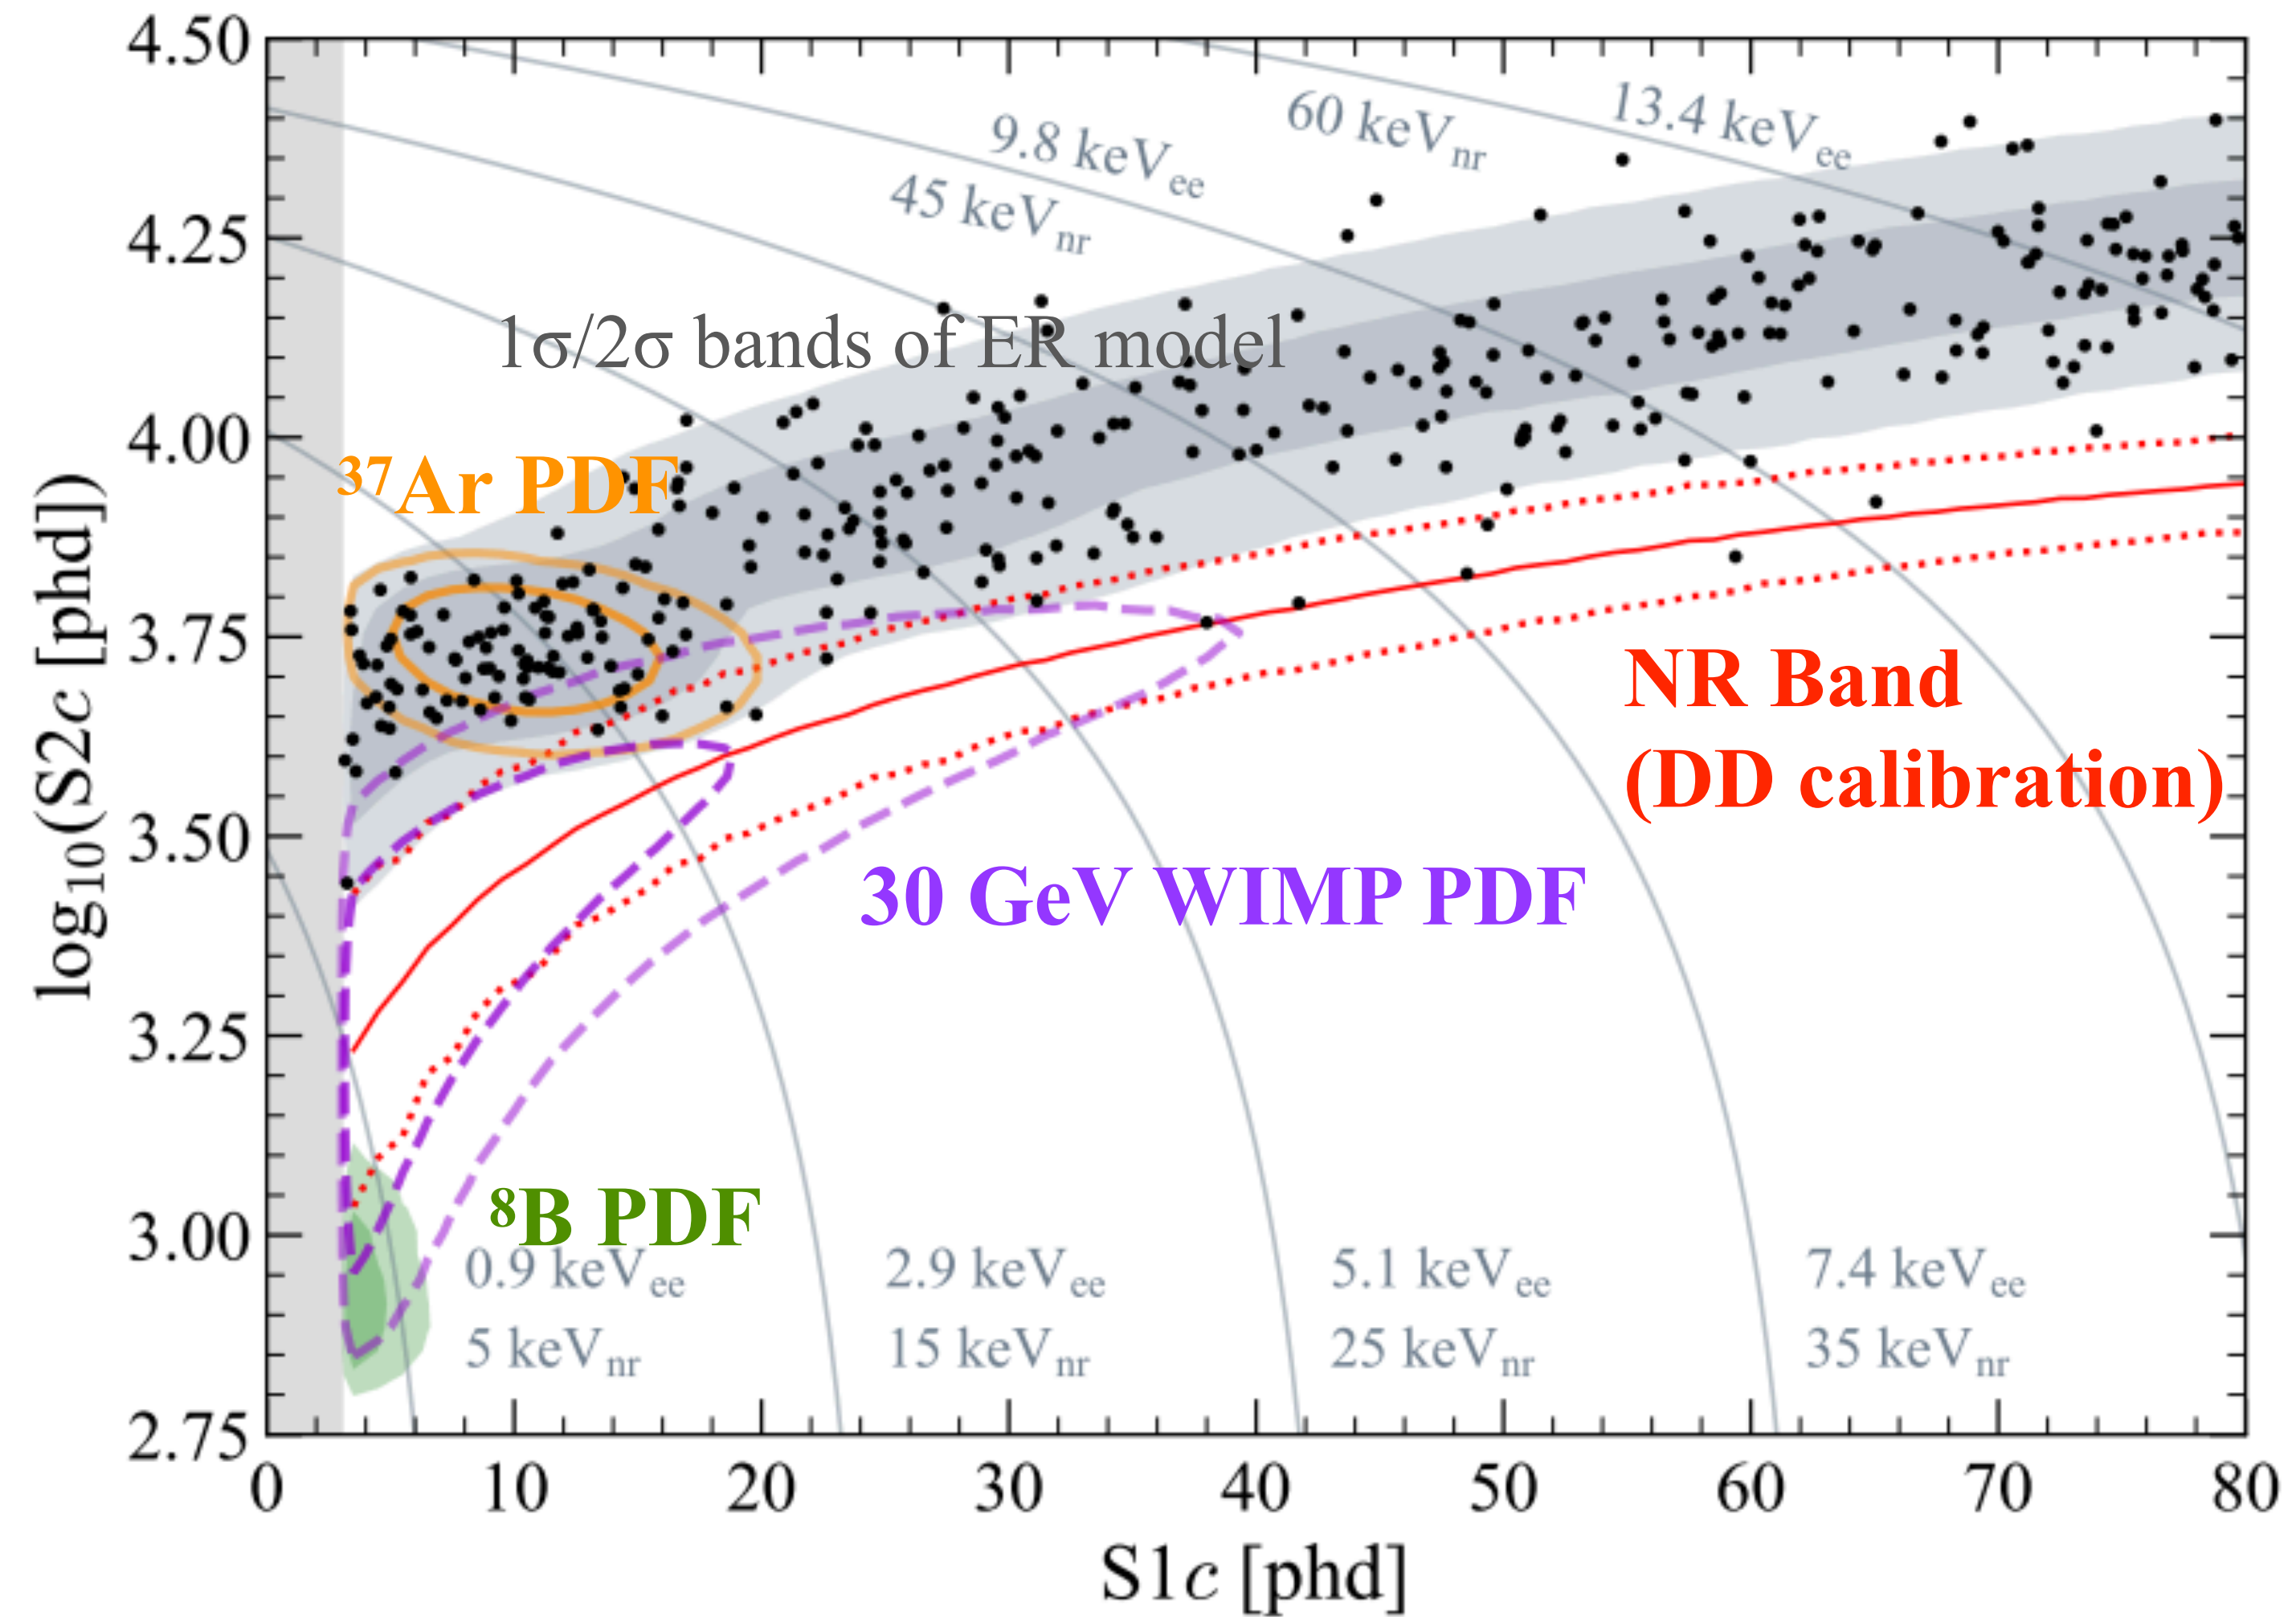

- **Events surviving all cuts in the 5.5 tonne fiducial volume (FV) are distributed uniformly**
 - Radial cut (4 - 5.2cm) driven by “wall-BG” (degraded S2 due to charge loss near the PTFE wall)
 - Vertical z cut ($86\mu\text{s} < \text{drift times} < 936.5\mu\text{s}$) is driven by gas events
- **Skin and OD prompt tag:**
 - Removes gammas
 - Skin reduces bare L,M-shell ^{127}Xe background 5x
- **OD (and skin) delayed tag:**
 - 1200 μs capture window, ~ 200 keV threshold
 - Provides in situ counting on neutron BG:
 - 0 +0.2 neutron events in SR1

Events after all cuts

- A total of 335 events after all cuts in the ROI
- 60 ± 1 live days
- 5.5 ± 0.2 tonne FV
- This is the input to PLR

Profile Likelihood Ratio

Parameters of interest: signal mean (μ_s)

Observables: (S_1, S_2)

Nuisance parameters: background means

$$\mathcal{L}(\theta) = \left[\text{Pois}(n_0 | \mu(\theta)) \prod_{e=1}^{n_0} \frac{1}{\mu(\theta)} \left(\mu_s f_s(\mathbf{x}_e | \theta) + \sum_{b=1}^{N_e} \mu_b f_b(\mathbf{x}_e) \right) \right] \prod_{p=1}^{N_e} f_p(\mathbf{g}_p | \mu_p)$$

Extended term

Constraint functions

Global observables: expected events

- Follow agreed statistics convention to report dark matter search ([Eur Phys J C \(2021\) 81:907](#))
 - Frequentist, two-sided, signal-strength is strictly positive, asymptotic limit is not used

PLR Fitting Results

Best fit is consistent with zero WIMP hypothesis at all masses

Source	Expected Events	Fit Result
β decays + Det. ER	218 ± 36	222 ± 16
ν ER	27.3 ± 1.6	27.3 ± 1.6
^{127}Xe	9.2 ± 0.8	9.3 ± 0.8
^{124}Xe	5.0 ± 1.4	5.2 ± 1.4
^{136}Xe	15.2 ± 2.4	15.3 ± 2.4
^8B CE ν NS	0.15 ± 0.01	0.15 ± 0.01
Accidentals	1.2 ± 0.3	1.2 ± 0.3
Subtotal	276 ± 36	281 ± 16
^{37}Ar	[0, 291]	$52.1^{+9.6}_{-8.9}$
Detector neutrons	$0.0^{+0.2}$	$0.0^{+0.2}$
30 GeV/ c^2 WIMP	–	$0.0^{+0.6}$
Total	–	333 ± 17

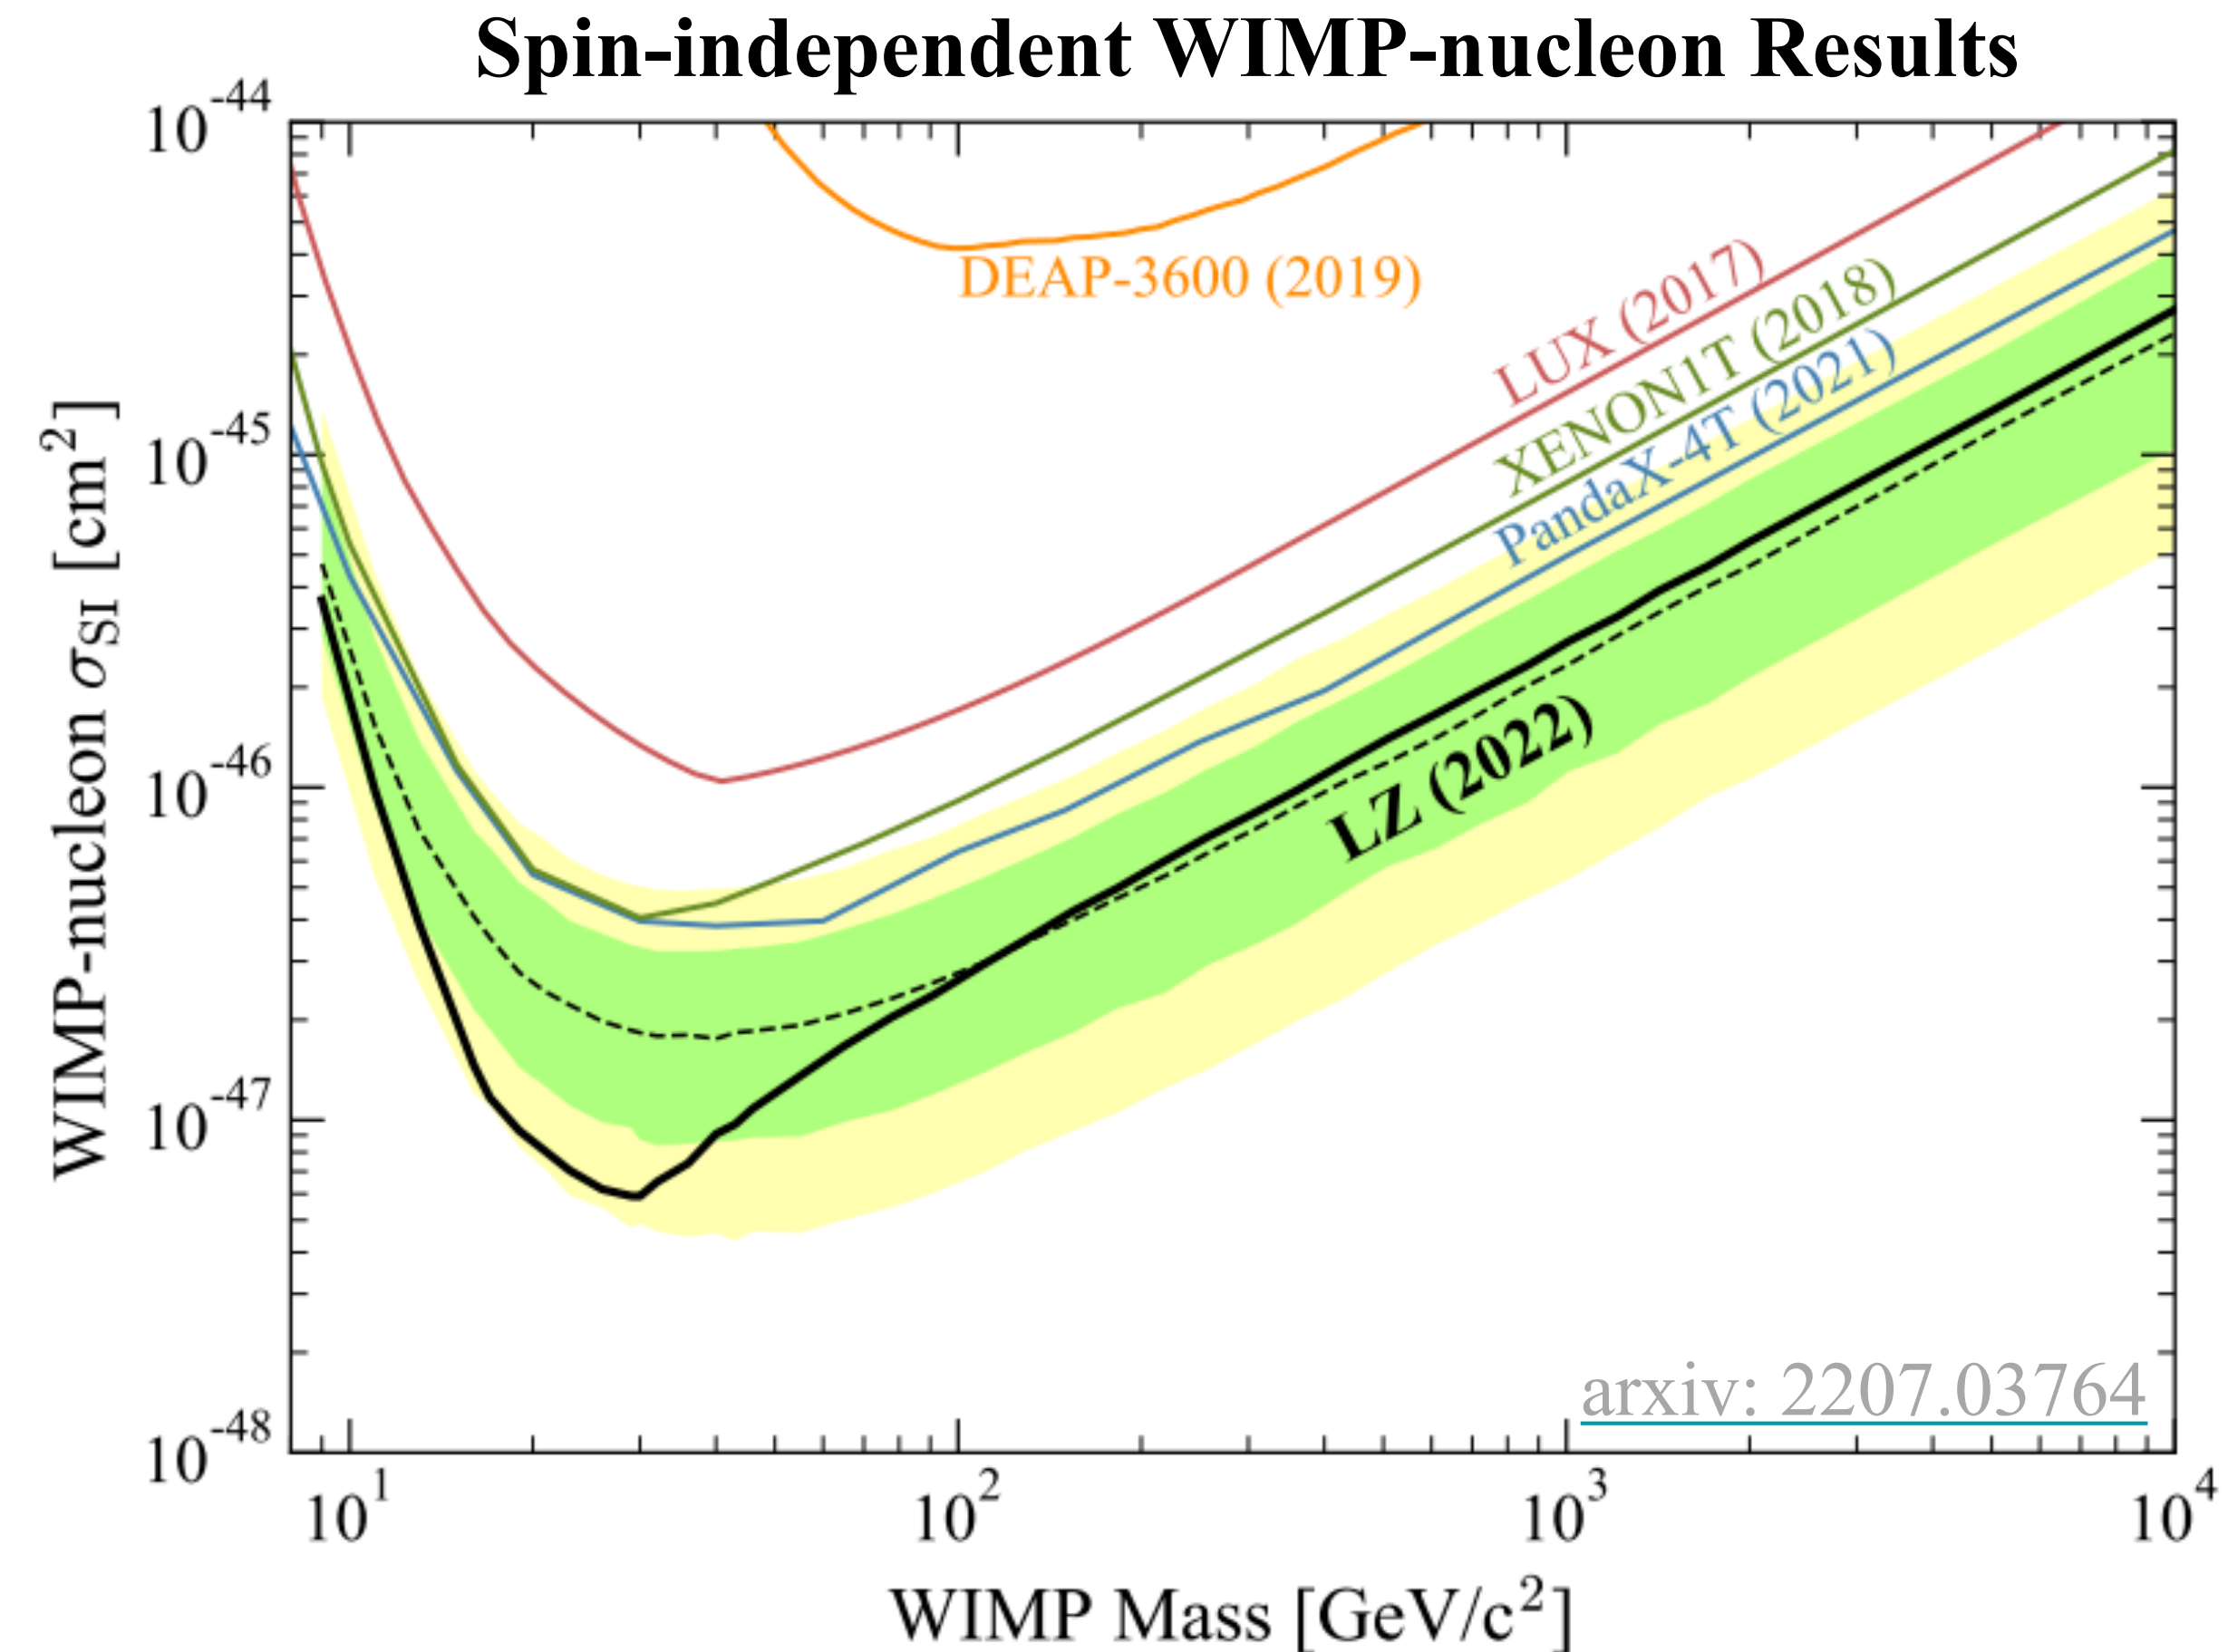

[arxiv: 2207.03764](https://arxiv.org/abs/2207.03764)

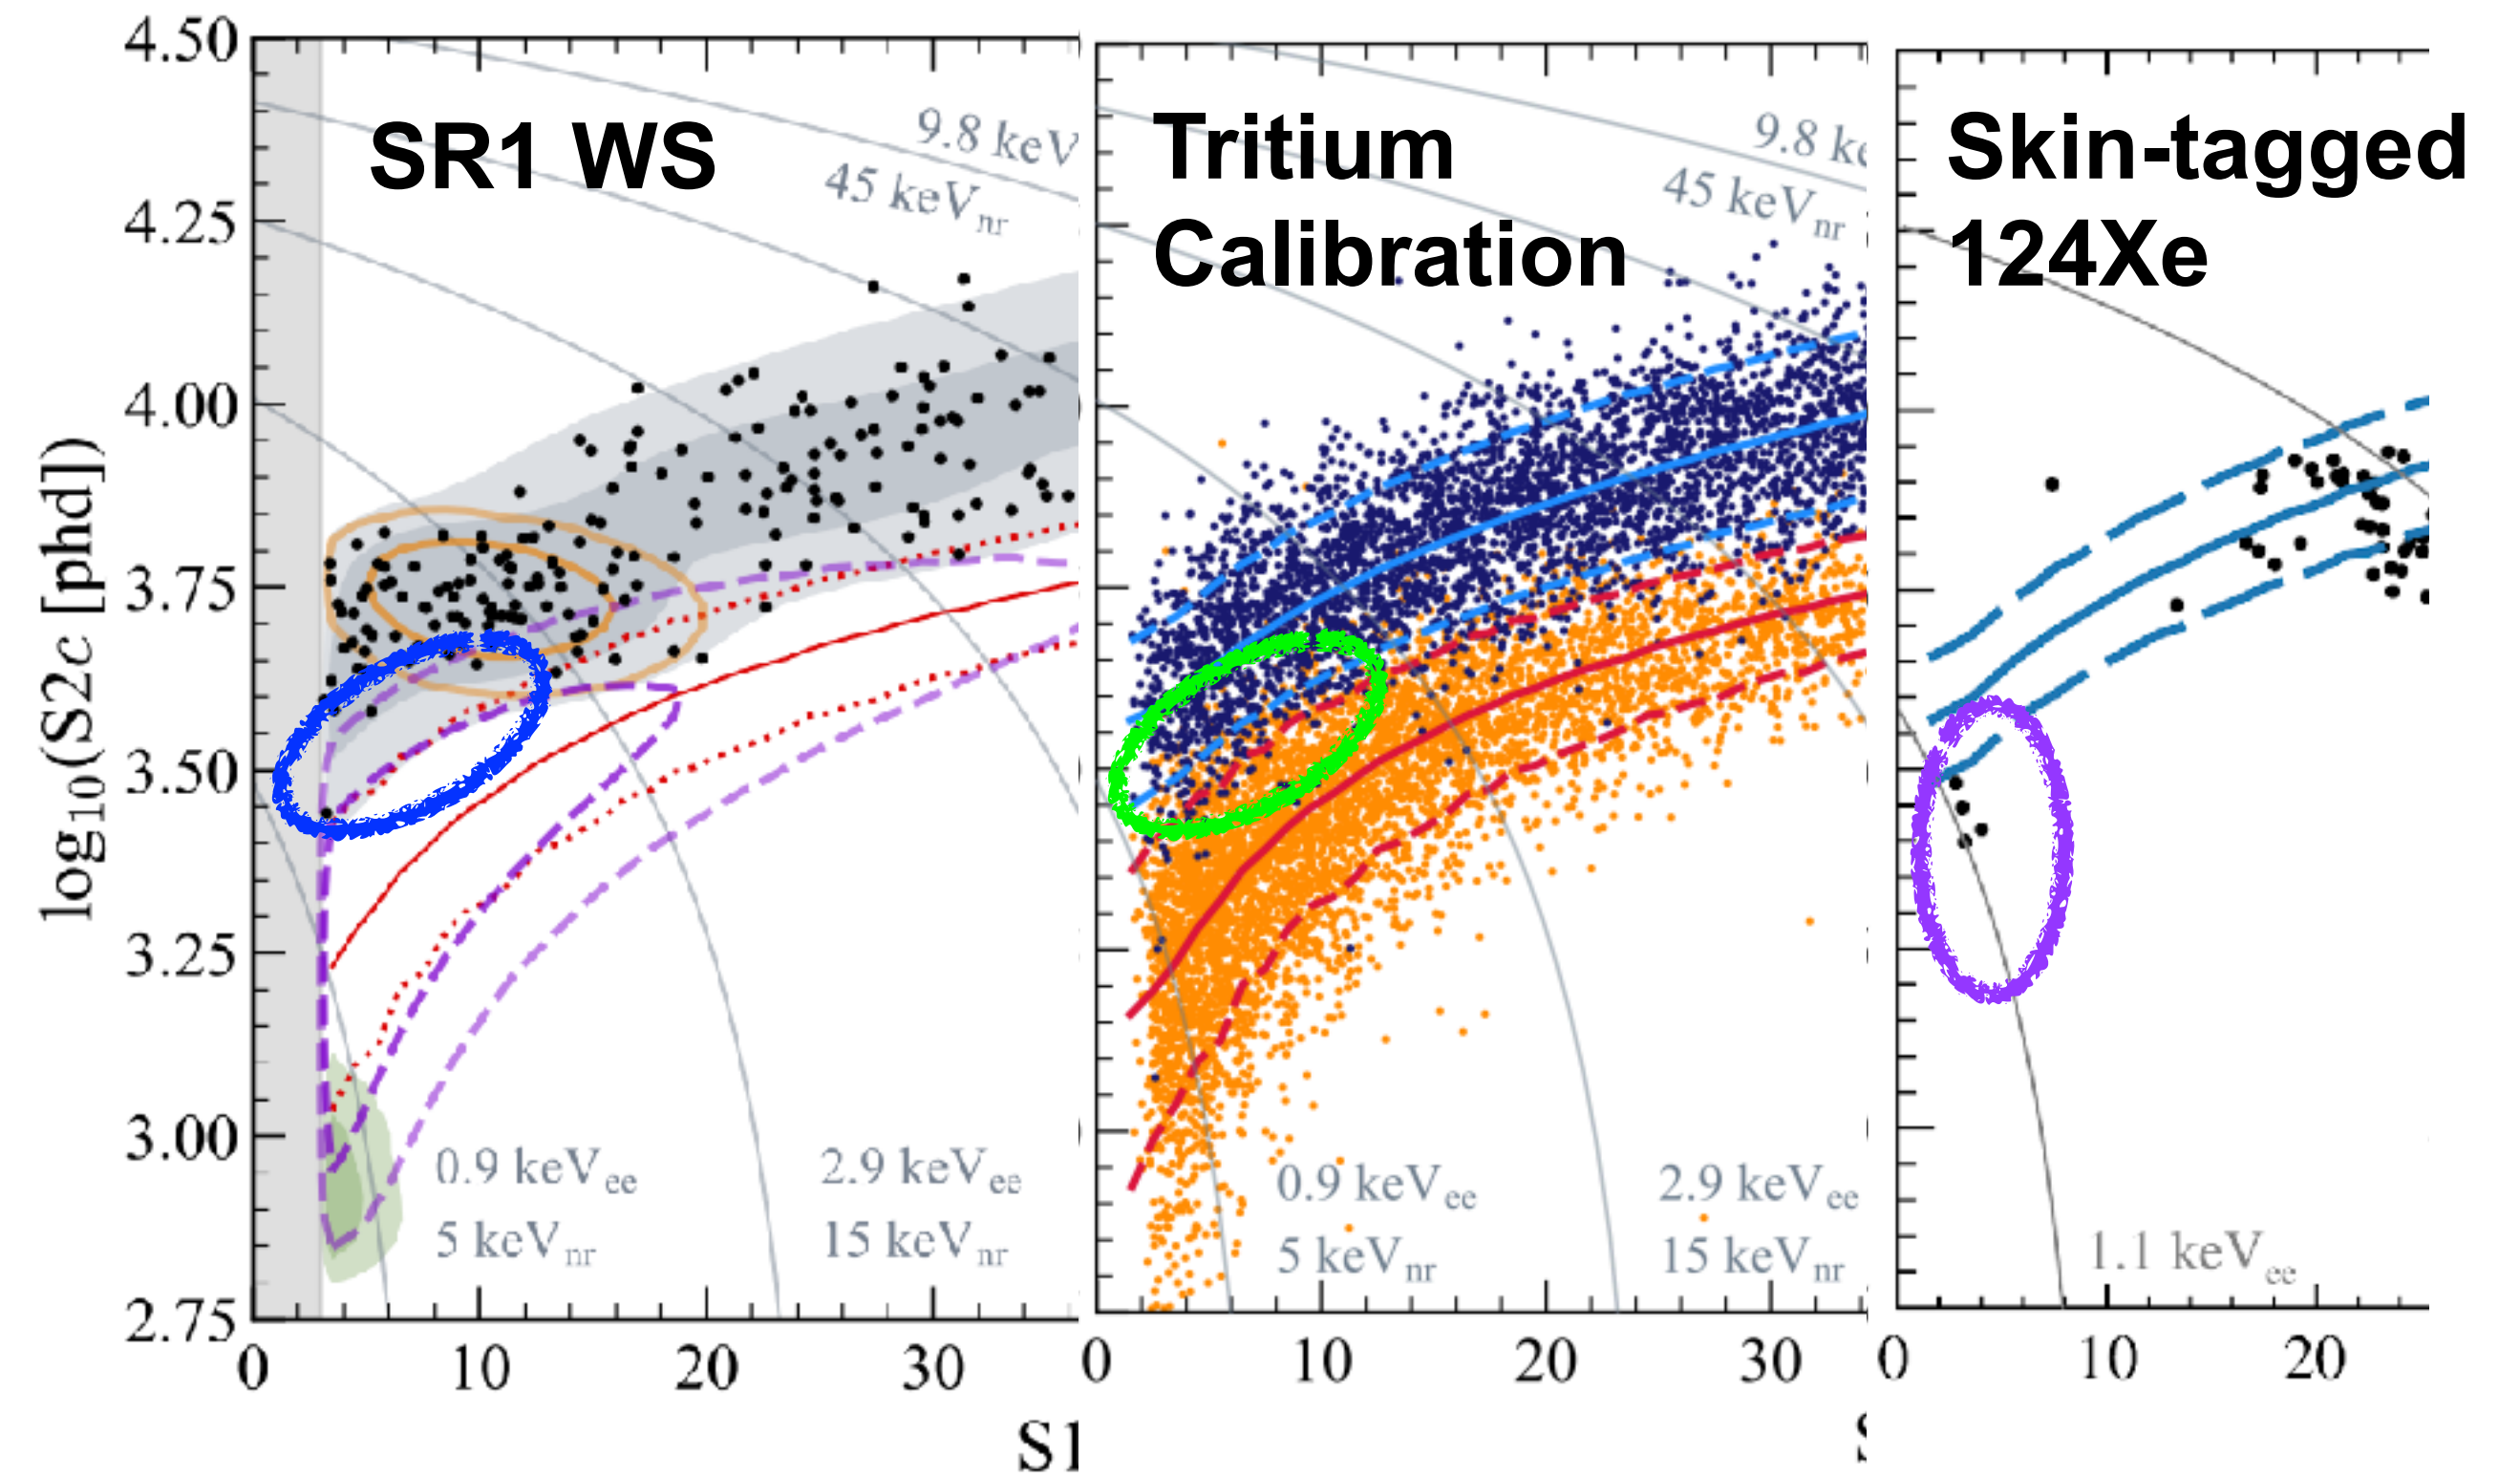

The Exclusion Limit

- Best limit (90% CL) on SI WIMP-nucleon cross section
 - Minimum $5.9 \times 10^{-48} \text{ cm}^2$ at 30 GeV
 - High mass matches expectation while low-mass benefits from the under-fluctuation of data
- A power constraint of $\Pi_{\text{crit}} = 0.32$ was applied (recommendation by [Eur Phys J C \(2021\) 81:907](#))

Downward fluctuation=> Power constrained limit

Downward fluctuation in the observed upper limit near 30 GeV

Deficit of events under ^{37}Ar population is observed
 However Tritium & DD data are well-covered in the same region (no deficit)
 Skin-tagged M-shell ^{124}Xe is consistent with expected count.

Conclusion: a statistical fluctuation; use power constrained limit

Where are we in the “Moore’s Law”?

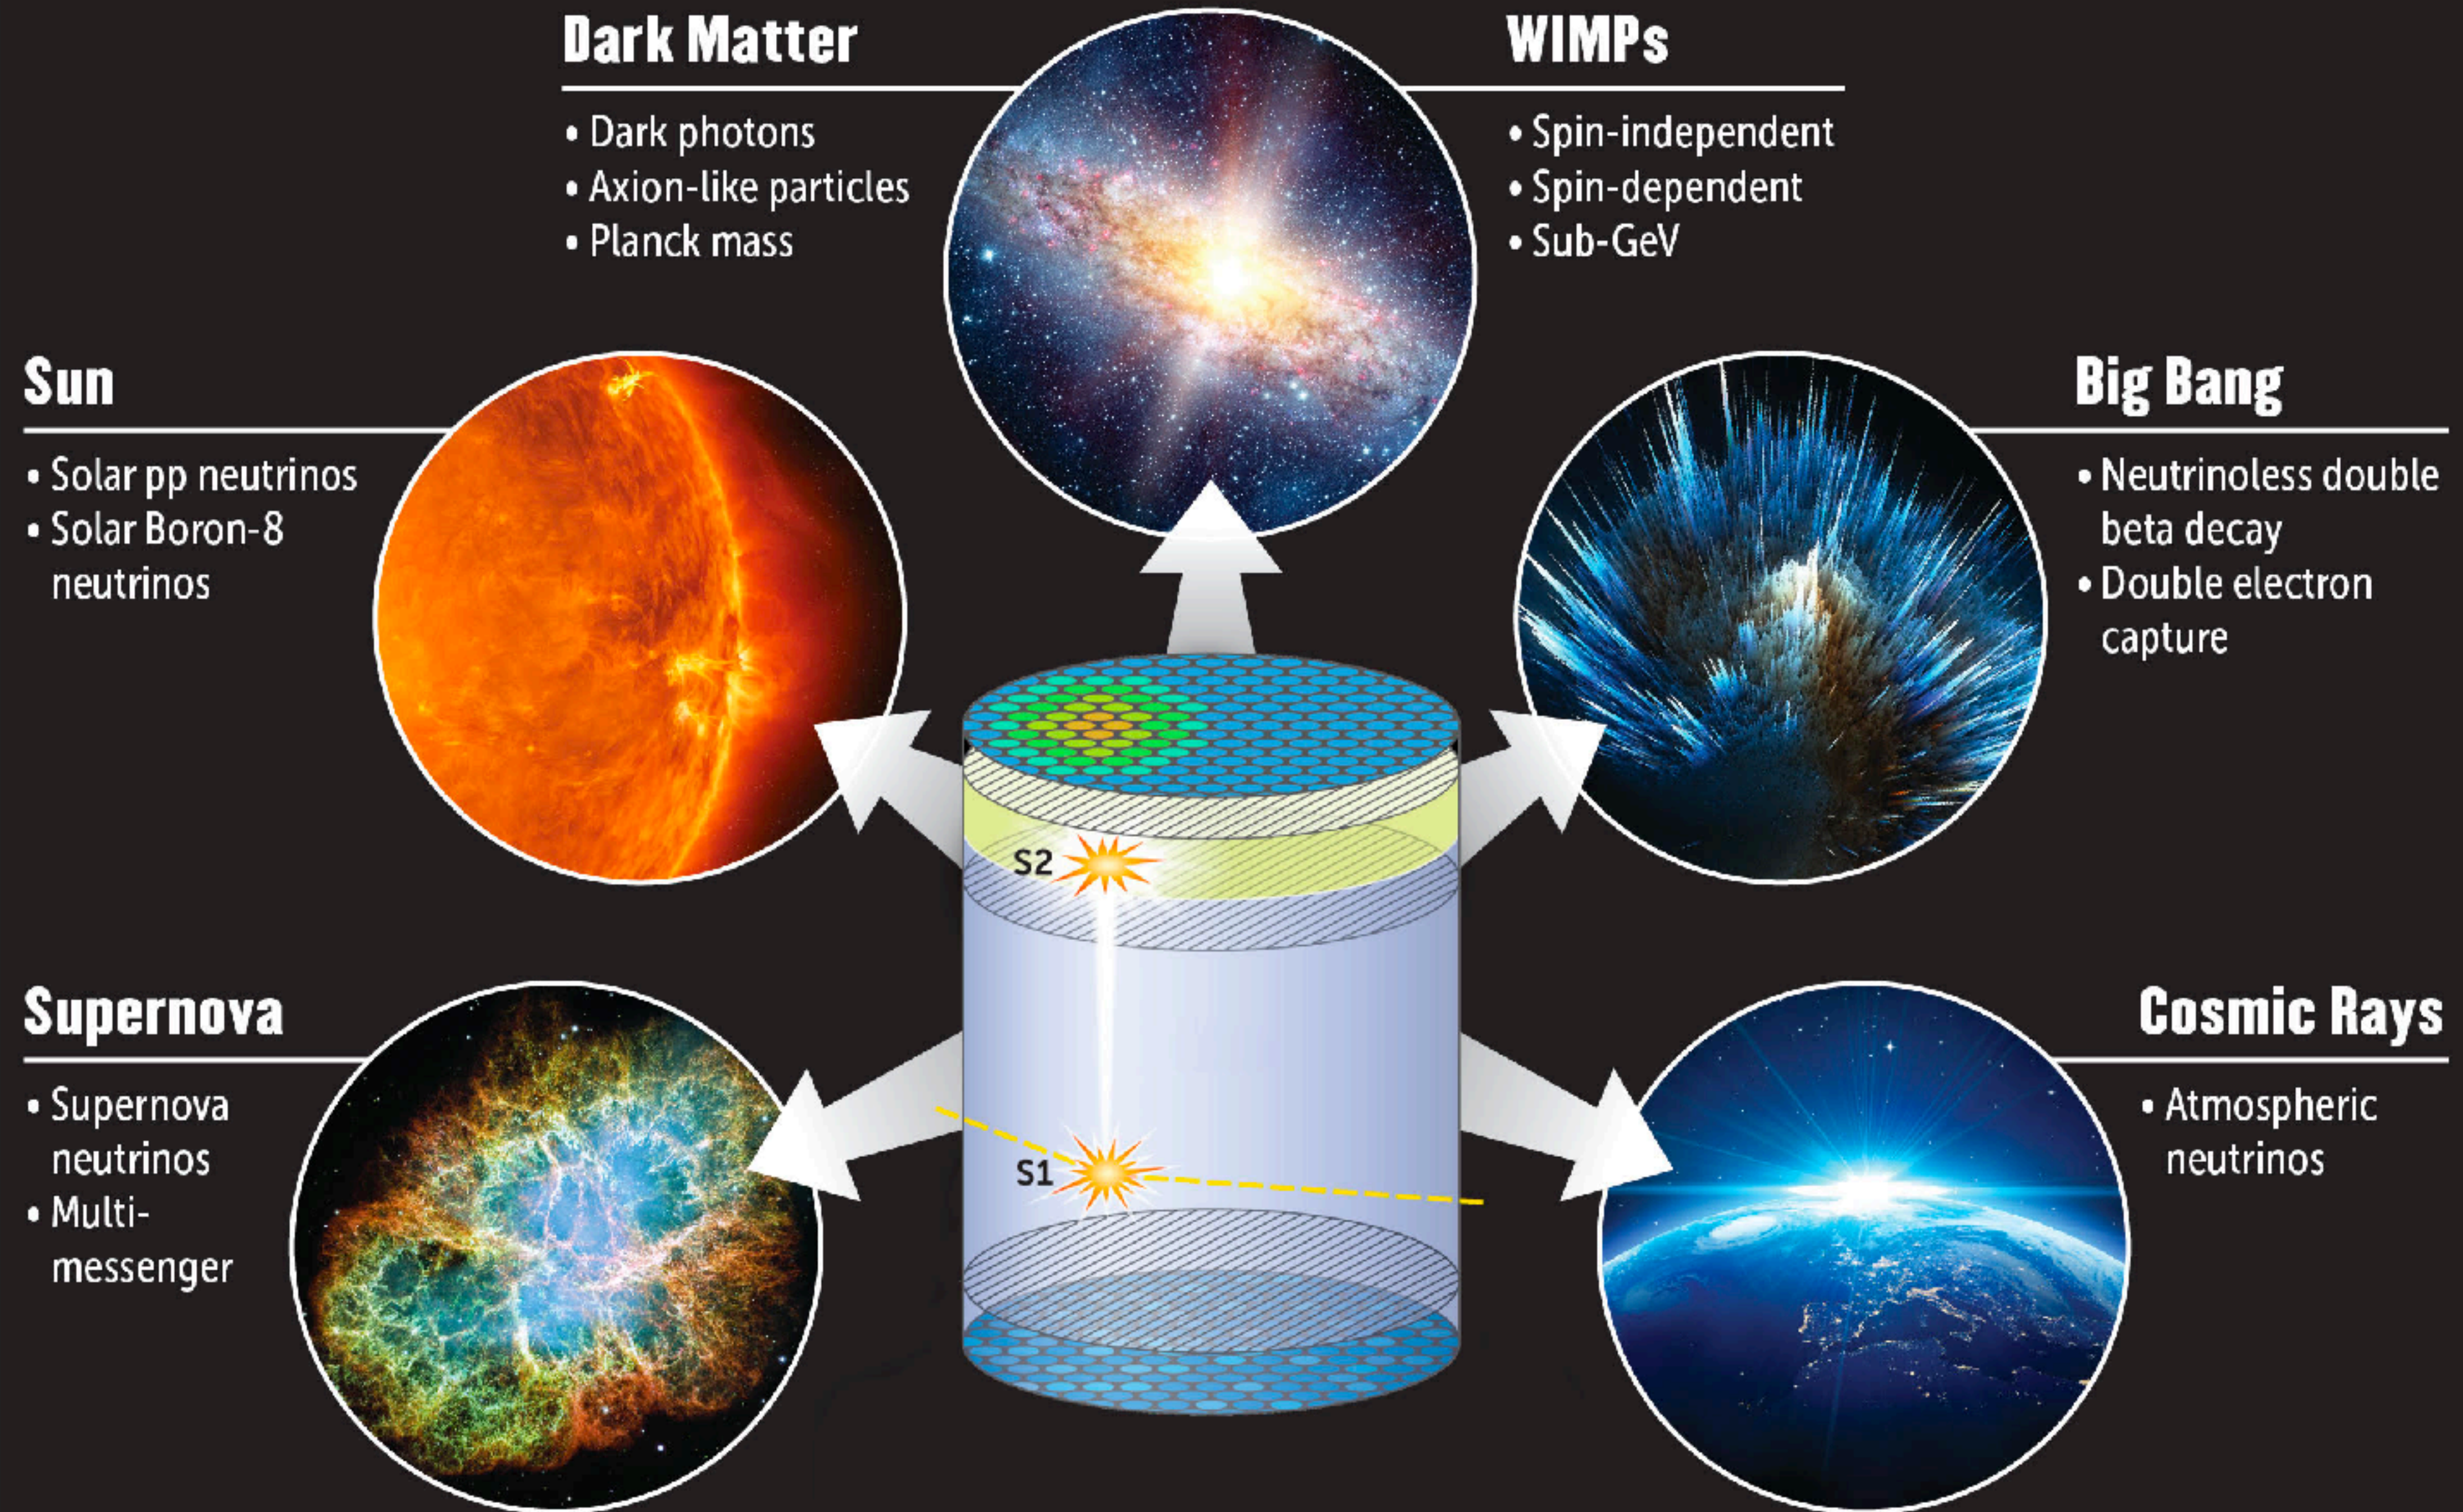

Best and on-track

Summary

- LZ is on commissioning and taking high quality physics data
- The SR1 found no evidence of dark matter, but its results demonstrates the potential to reach new physics
- Xenon community is united as XLZD

Microphysics of Xenon

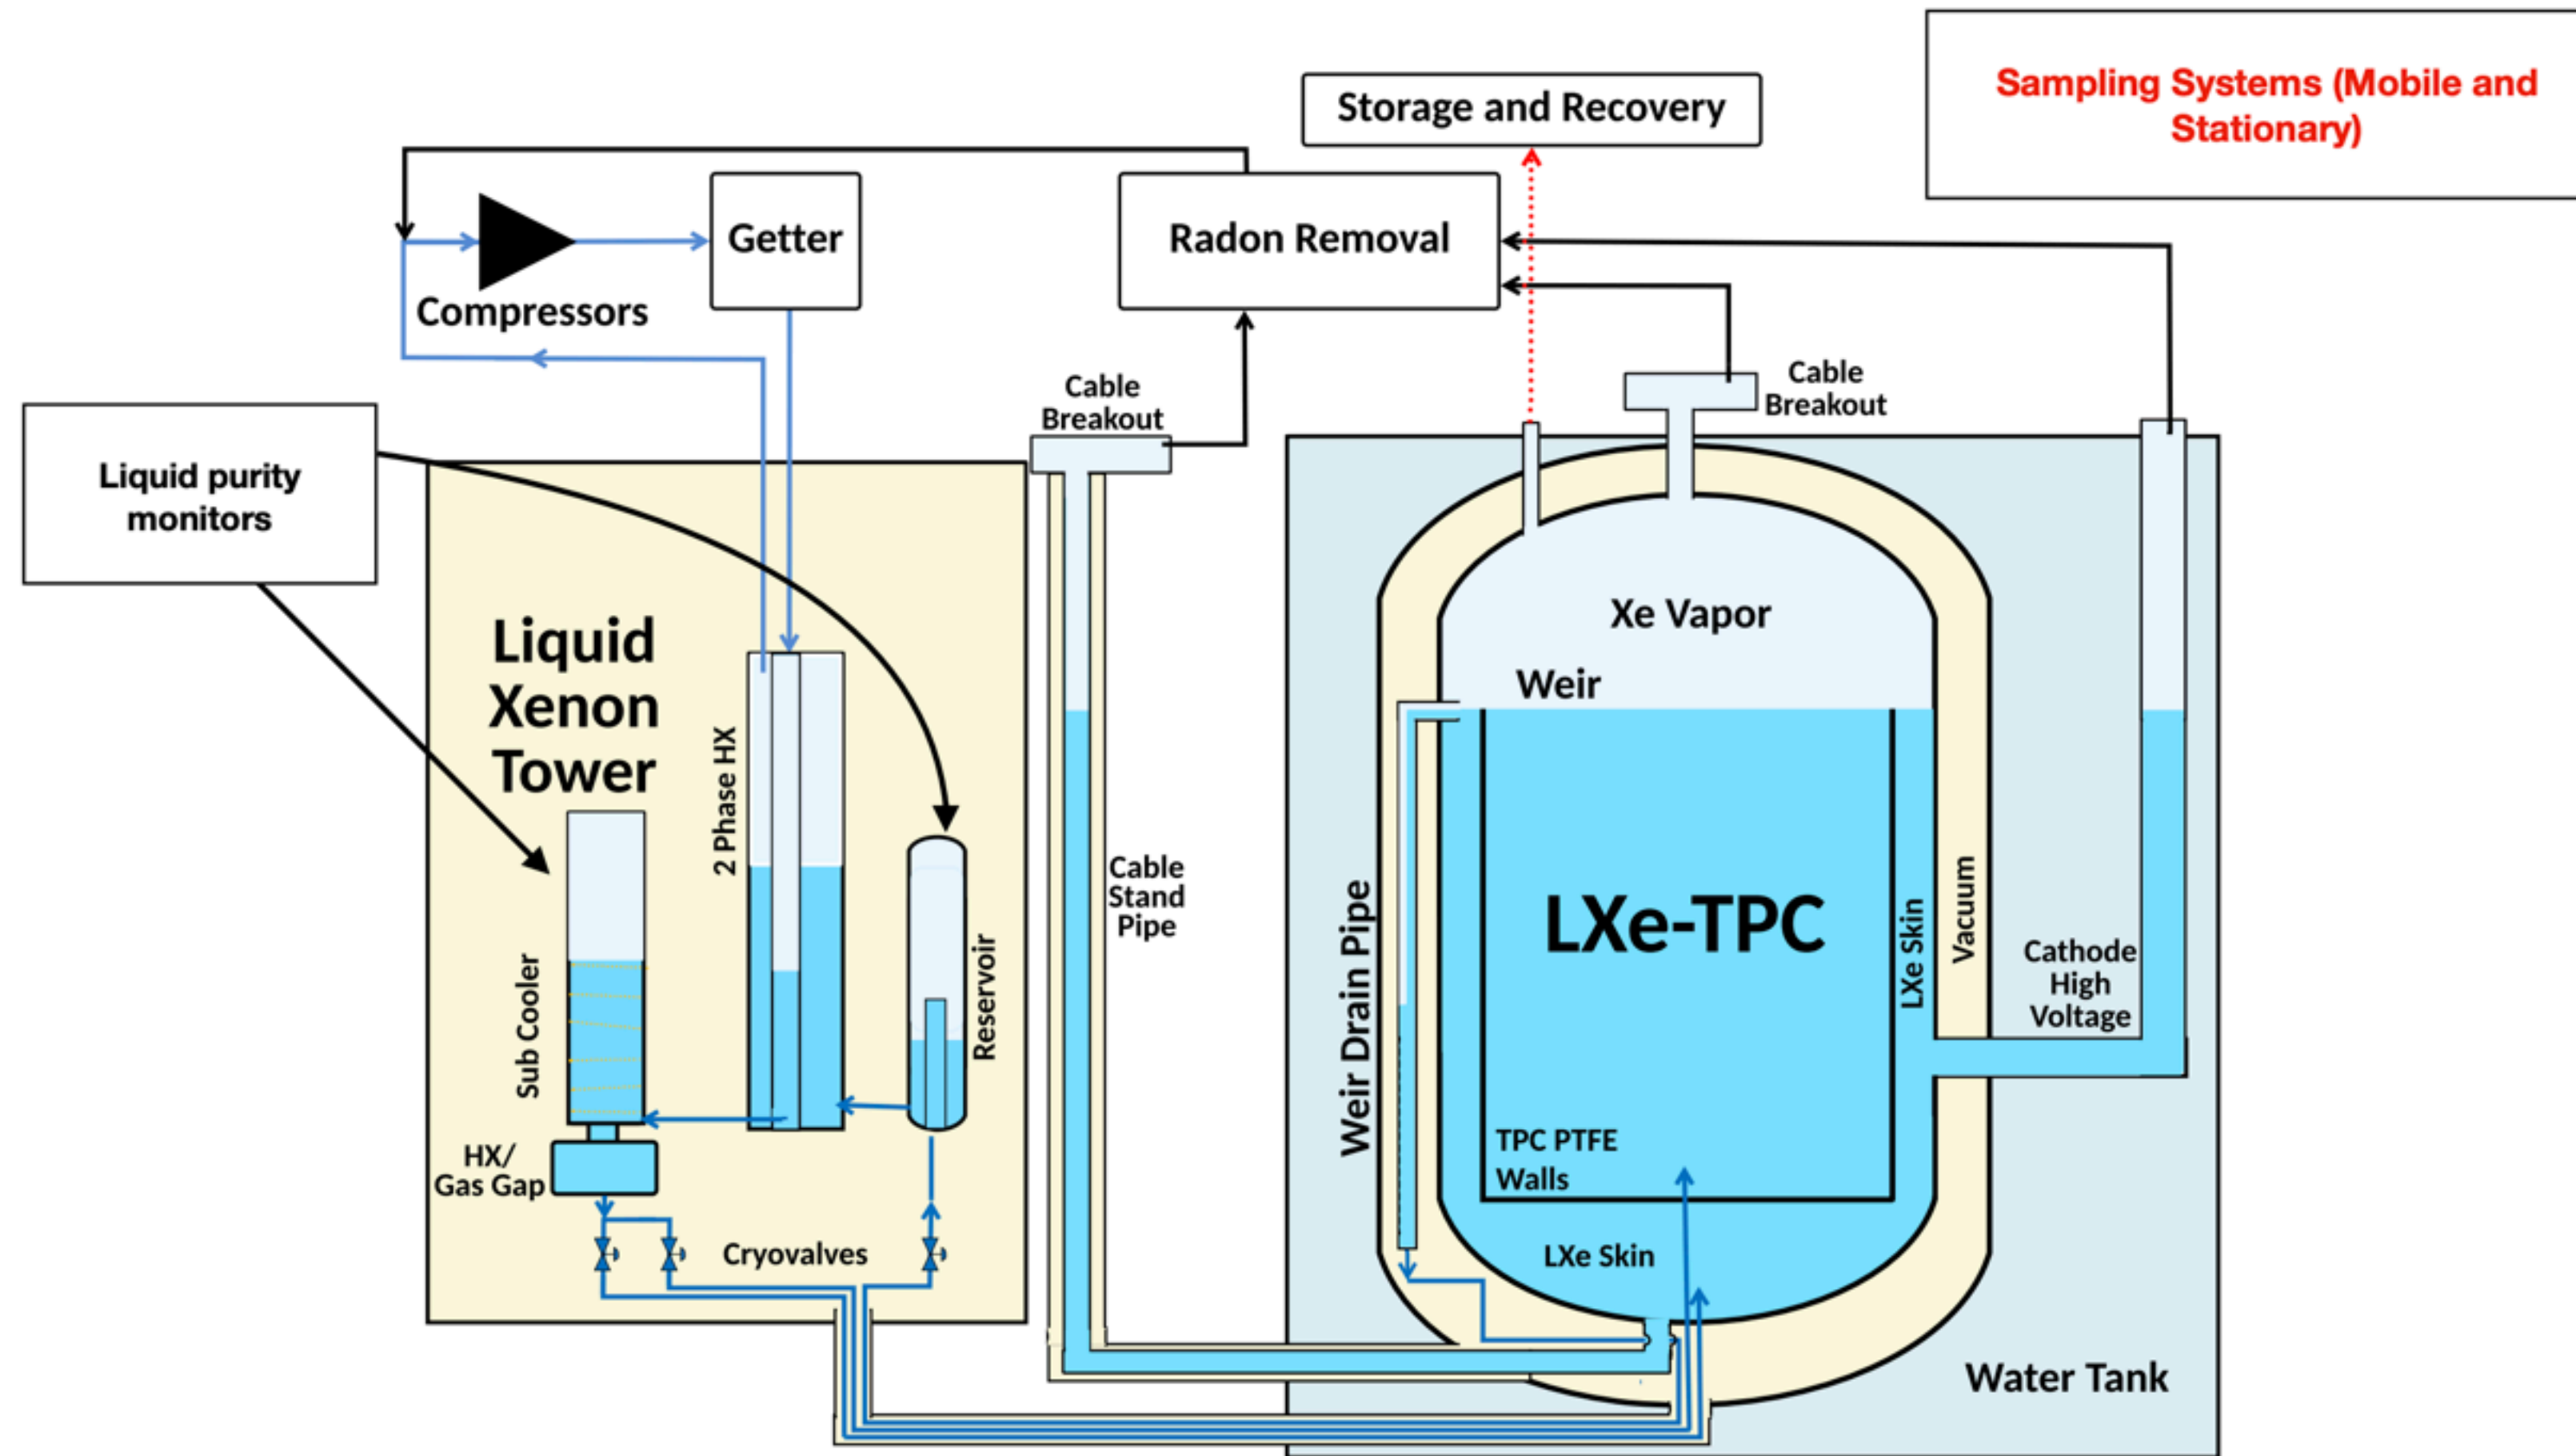

FIG. 1. Decay scheme of ^{127}Xe [25] with units of keV. The ^{127}Xe decays via electron capture to ^{127}I . The percentage above the transition arrow is the gamma-ray intensity as fraction of parent (^{127}Xe) decay.

Circulation System

Credit: David Woodward

Fit Uncertainty from PLR

- Except for betas and ^{37}Ar , backgrounds have tight constraints from sideband analysis or external measurements
- Fit in statistical dominant region, and the impact from constraint is relatively small,
- The fit uncertainties do shrink a little bit, but below the statistical fluctuation.
- Final result has good agreement between data and fit output model

Source	Expected Events	Best Fit
β decays + Det. ER	218 ± 36	222 ± 16
ν ER	27.3 ± 1.6	27.3 ± 1.6
^{127}Xe	9.2 ± 0.8	9.3 ± 0.8
^{124}Xe	5.0 ± 1.4	5.2 ± 1.4
^{136}Xe	15.2 ± 2.4	15.3 ± 2.4
^8B CE ν NS	0.15 ± 0.01	0.15 ± 0.01
Accidentals	1.2 ± 0.3	1.2 ± 0.3
Subtotal	276 ± 36	281 ± 16
^{37}Ar	[0, 291]	$52.1^{+9.6}_{-8.9}$
Detector neutrons	$0.0^{+0.2}$	$0.0^{+0.2}$
30 GeV/ c^2 WIMP	–	$0.0^{+0.6}$
Total	–	333 ± 17

Why Power Constraint not following -1σ ?

- LZ follows the convention from [community-wide, statistical white paper](#) to power constrain its limits
- The discovery power threshold was chosen to be 0.32, corresponds to -1 sigma for a Gaussian case
- Due to low event count, the discovery power is highly enhanced — even a very small value of the will satisfy the discovery power requirement.
- Top plot: departure from the 1 sigma contour at low number of expected background events in a Gaussian toy simulation
- Bottom: confirmation that we “hug” the -1 sigma contour when the expected number of detector NR events is increased from 0 to 100

Credit: Jelle A

Credit: Xin X.

Why p-value is so good?

- We chose the binning for the reconstructed energy spectrum to best show the resolution of the ^{37}Ar peak
- If we look at other observables (e.g. reduced ER band) or rebinning in Erec, the p-value returns other values, which show that the data is not inconsistent with the background-only model
- This appears to be a random fluctuation

Why purity dropped?

- A problem in operational activity caused the reservoir that the detector drains into to rapidly empty of liquid xenon
- This caused displacement of xenon and electronegative impurities, contaminating the main system
- Overall, the duration of the event was ~10 minutes
- The impurities were removed by the getter as expected, and the purity recovered quickly
- The second circulation change was to perform source injection calibrations with increased liquid mixing in the TPC

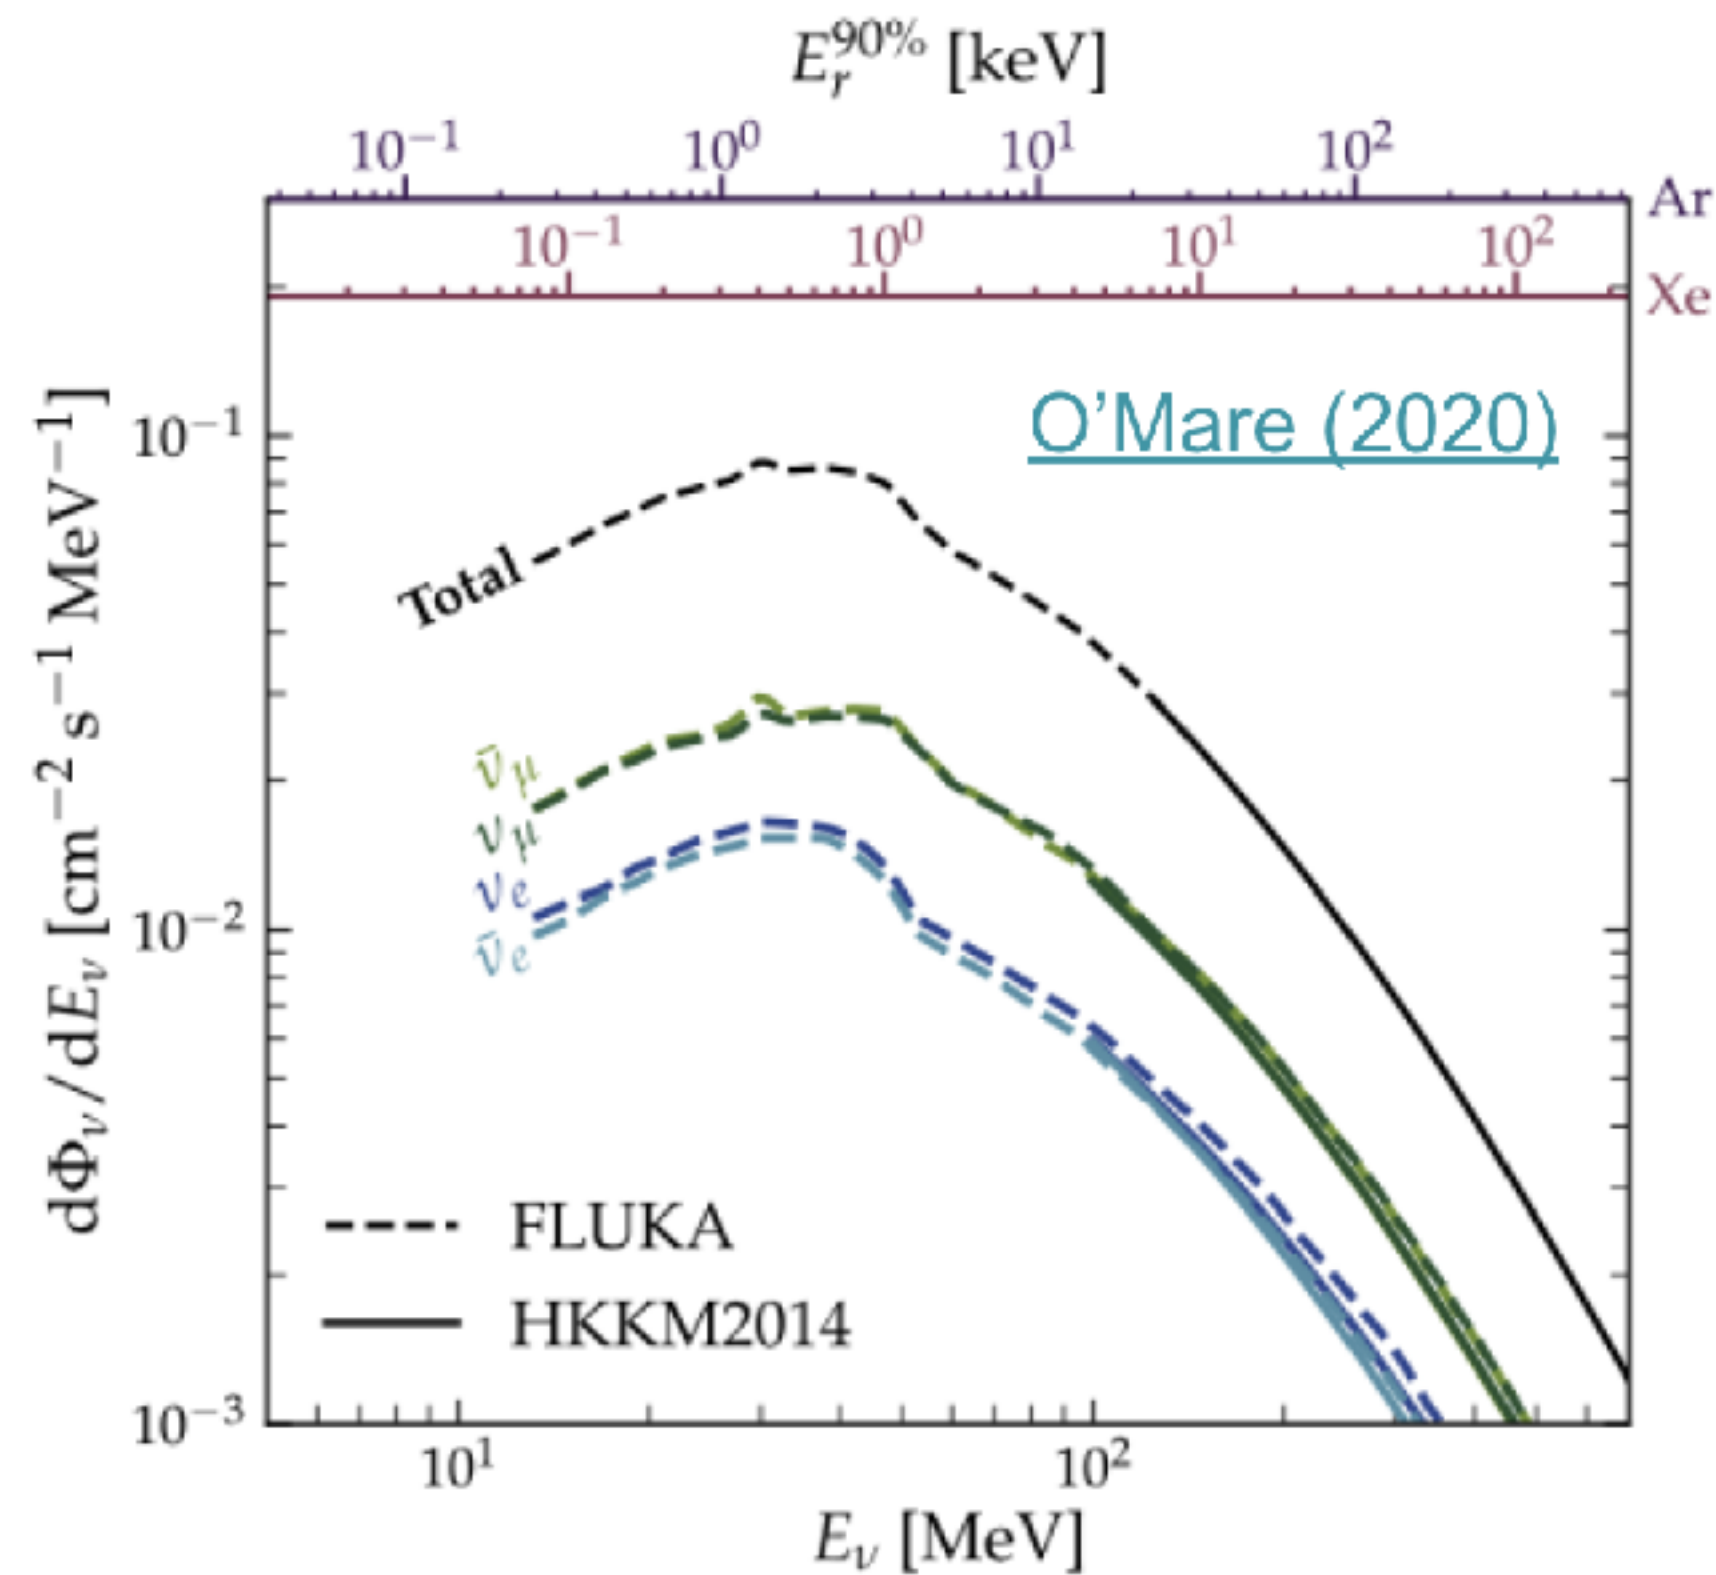

Status of Ar37 in LZ?

- For the SR1 WIMP search, we include ^{37}Ar as a background, but do not include any time dependence in the analysis
- We do see a decrease of rate in ^{37}Ar energy region over the run period
- This does not preclude some other signal sitting underneath the ^{37}Ar peak
- Work in progress to include time-dependence in a search for low energy ER signals

Atmospheric Neutrino and the Neutrino Floor (Fog)

Atm. Neutrino Flux Uncertainty:

- Current **20% ($E_\nu < 100$ MeV)**, 15% ($E_\nu < 1$ GeV) u/c from calculation [[Honda 2011](#)]. No direct experimental measurement for sub-GeV.
- Future experimental constraint (not necessarily a completed list):
 - *DUNE* [[K. J. Kelly 2019](#)]: 0.1 - 1 GeV range
 - *Hyper-Kamiokande* [[Z. Li 2017](#)], 100 MeV - 10 TeV
 - *JUNO* [[G. Settanta 2019](#)], 0.1 GeV - 10 GeV range, projected u/c: 10% to 25%

Effect on WIMP Sensitivity (neutrino floor/fog)

- An generic LXe detector simulated by [NEST](#)
 - NR efficiency curve is similar to LZ (slide 10, black curve)
 - Total ER leakage: 10^{-4} below NR median
- Backgrounds considered (Rn is ignored):
 - Atmospheric neutrino (20% u/c)
 - *pp* neutrinos
 - $^{136}\text{Xe } 2\nu\beta\beta$ (N.A., $T_{1/2} = 2.11 \times 10^{21}$ yr [[EXO-200](#)])
- PLR Setting:
 - Two-sided, Frequentist, $\mu_s > 0$, ... [[arxiv: 2105.00599](#)]

Opportunity: the First ^8B Observation via $\text{CE}\nu\text{NS}$

- ^8B has never been observed in $\text{CE}\nu\text{NS}$ channel. This is exciting!
- Events populate near threshold (purple).
- The expected event rate ($\text{FV}=5.6\text{e}3 \text{ kgd}$) is sensitive to the thresholds (preliminary):
 - LZ threshold (3-fold, $N_{ee}\geq 5$): $(2.7 \pm 0.69^{\text{yield}}) \text{ evt}/100 \text{ day}$
 - Lower threshold (2-fold, $N_{ee}\geq 5$): $(12 \pm 2.3^{\text{yield}}) \text{ evt}/100 \text{ day}$
- A significant claim is not a matter of if, but a matter of when

NEST Simulation of ^8B Rate in 100 day (preliminary)
 (Assuming efficiency from the right plot)

	3-fold ($S1 \geq 3 \text{ phd}$)	2-fold ($S1 \geq 2 \text{ phd}$)	S2-only (0 or 1 phd)
$N_{ee} \geq 8 \text{ e-}$	1.39	5.32	23.6
$N_{ee} \geq 7 \text{ e-}$	1.78	7.1	37.8
$N_{ee} \geq 6 \text{ e-}$	2.23	9.42	58.4
$N_{ee} \geq 5 \text{ e-}$	2.73	12.1	91.7
$N_{ee} \geq 4 \text{ e-}$	3.25	15.4	142
$N_{ee} \geq 3 \text{ e-}$	3.73	18.8	217

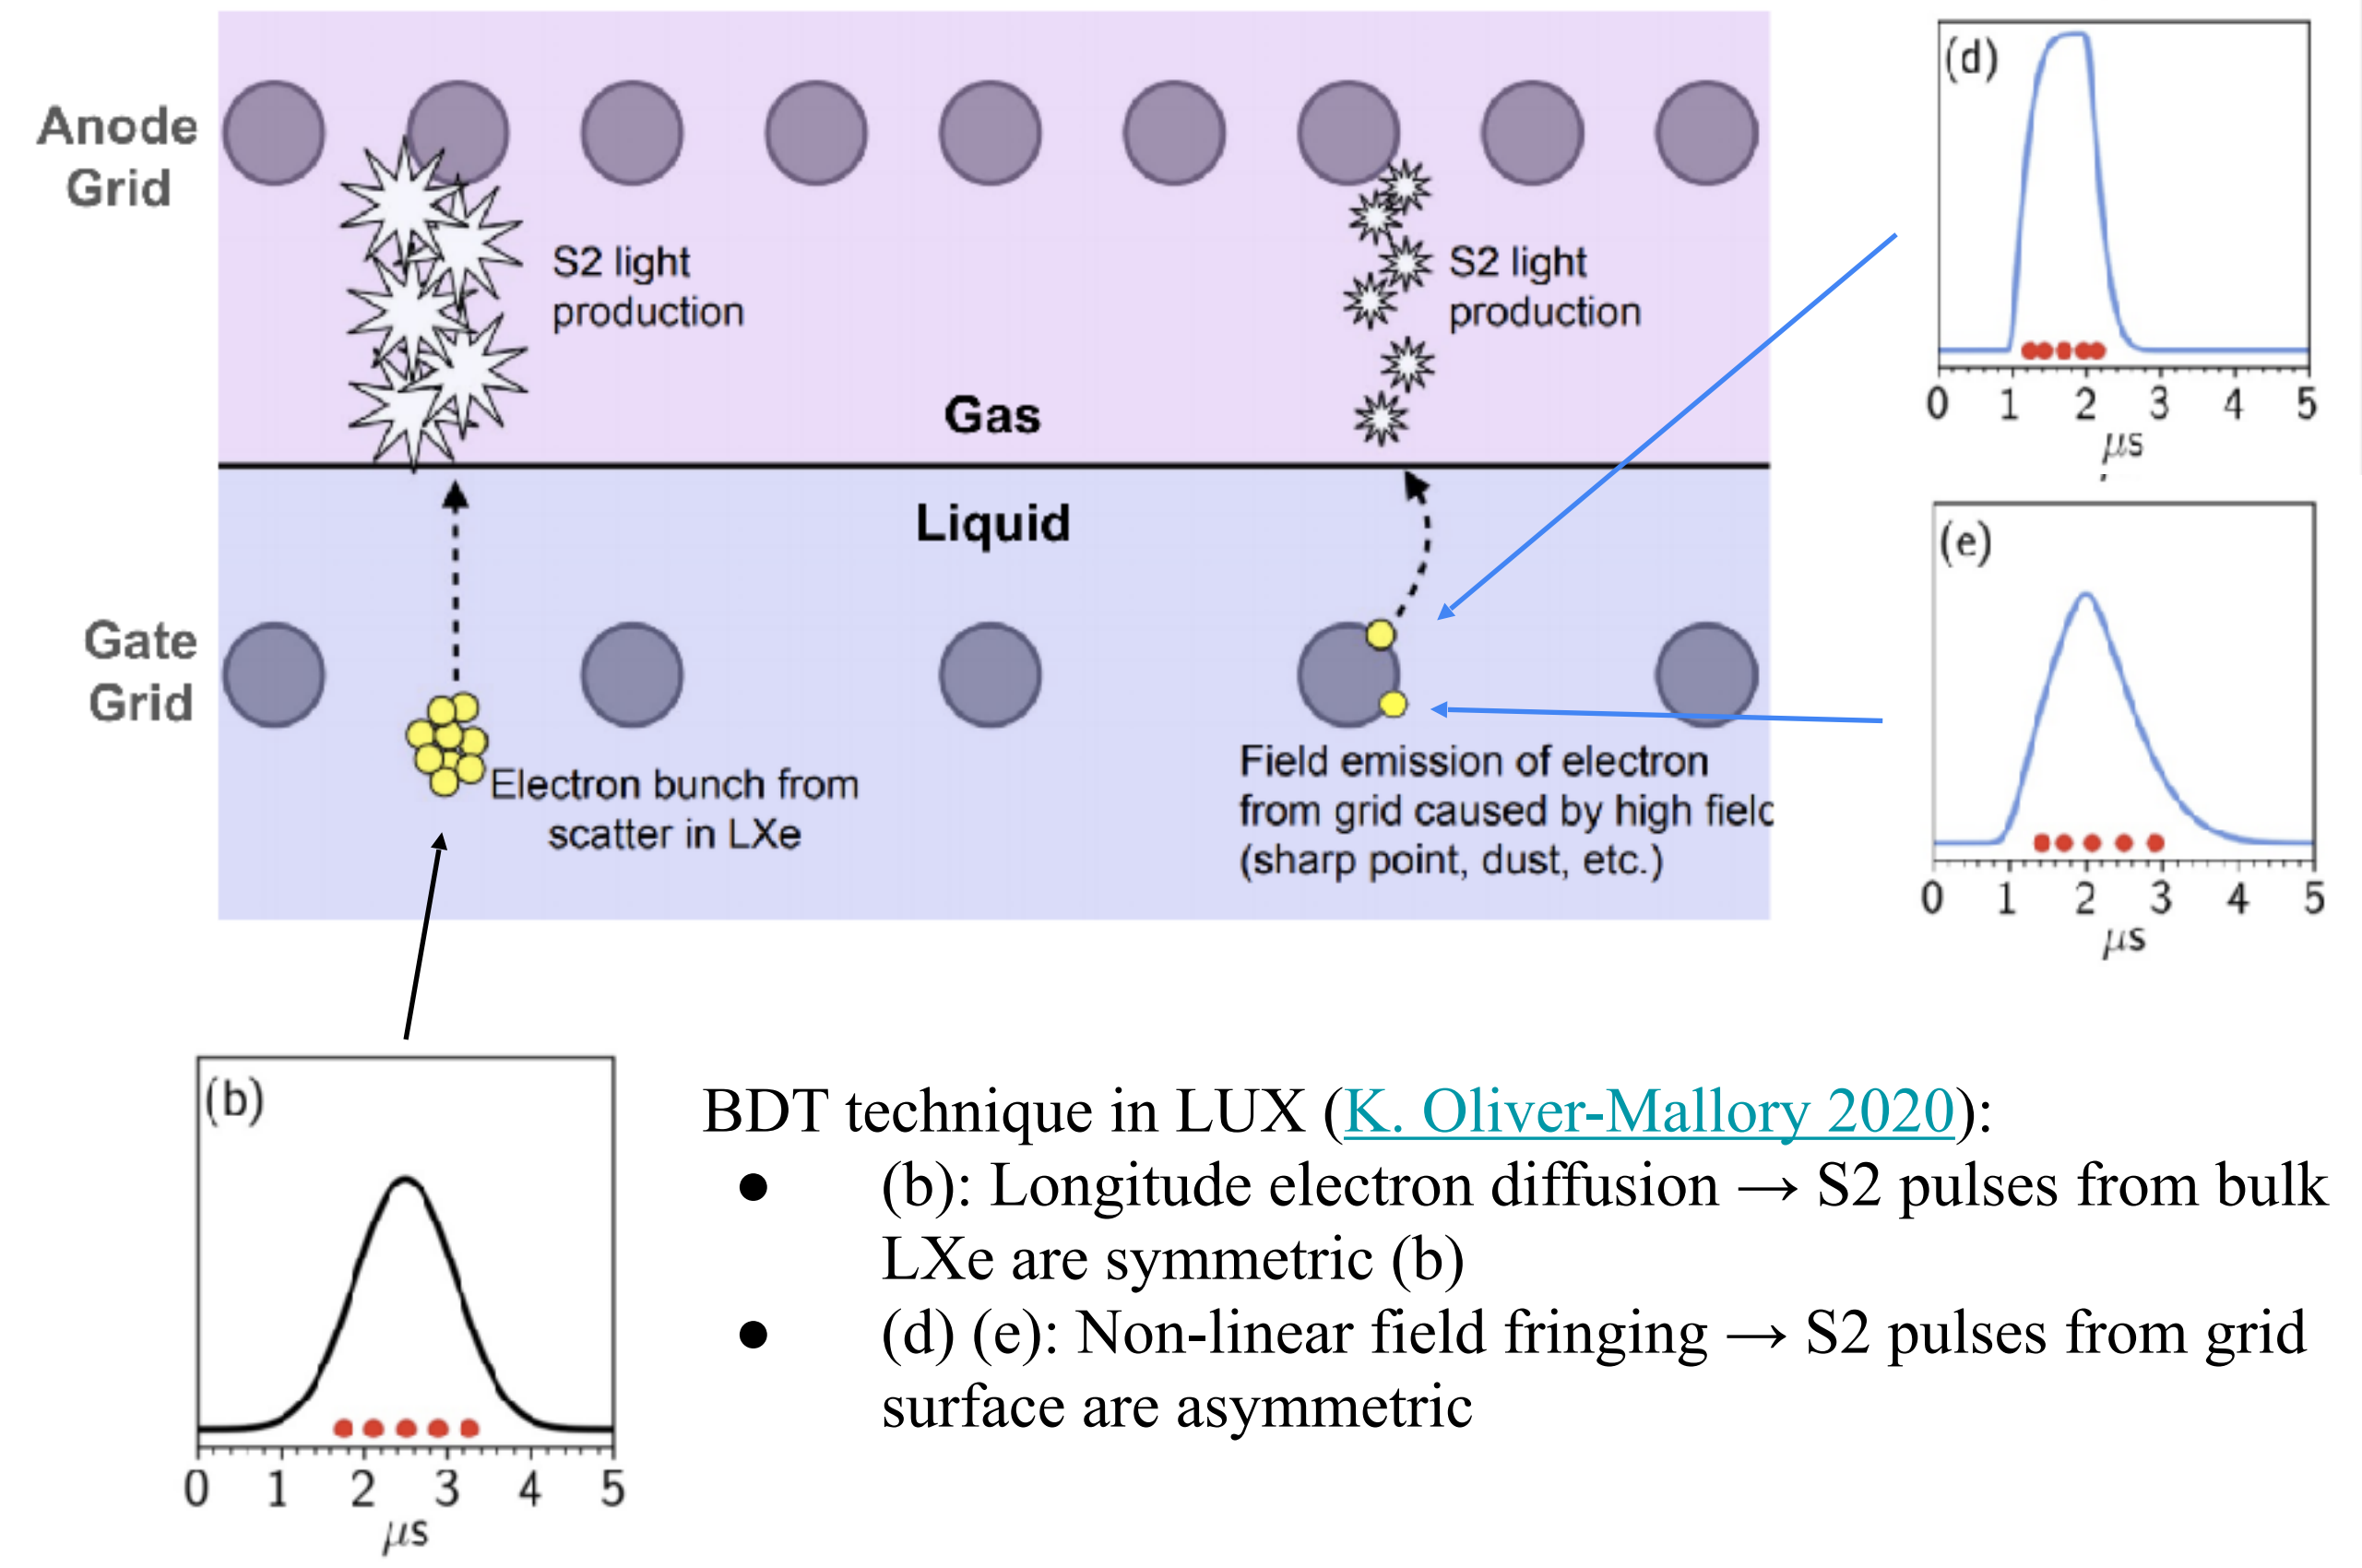

Challenge: Accidental Coincidence

- An accidental coincidence event occurs when an isolated S1 randomly pile-up with an isolated S2
- Possible sources of isolated S1:
 - Dark count pile up
 - Cherenkov in PMT windows / PTFE wall
 - Energy deposition occurs in non-drifting region
- Possible sources of isolated S2:
 - field electron emission from gate and cathode grids
 - delayed electron emission following S2s (ex. electron trapped at liquid surface or captured by impurity)
 - radiogenic grid emission
- Data-driven Modeling
 - Find isolated S1 events and isolated S2 pulse, and randomly pair them up (top plots)

- BDT technique in LUX ([K. Oliver-Mallory 2020](#)):
- (b): Longitude electron diffusion → S2 pulses from bulk LXe are symmetric (b)
 - (d) (e): Non-linear field fringing → S2 pulses from grid surface are asymmetric

- Features & Rejection:
 - Asymmetric S2 pulse shape (Machine Learning)
 - Drift time is uncorrelated to electron diffusion (Drift time vs S2 width)
 - Correlate with PMT that has abnormally high DC rate (PMT tagging)

- Ton-scale LXe detector is sensitive MeV-scale natural neutrinos via CEvNS
- Opportunity for LZ to make the first detection of ^8B in CEvNS channel
- CEvNS presents challenges for WIMP searches
 - Above 100 GeV: hard neutrino floor (fog) due to atm. uncertainty
 - 4-10 GeV: neutrino floor (fog) due to ^8B uncertainties (light yield)
 - Short-term impact is subdominant to Poisson fluctuation .
 - Long-term impact on sensitivity → **improvement in light yield measurement is crucial**
 - 10 GeV - 100 GeV: soft neutrino floor (fog) due to different spectrum shape between WIMP and atm neutrinos
- Next Generation Liquid Xenon experiment may (aside from WIMP search) measure:
 - solar pp (*Weinberg's angle* $\sin^2\theta_W$) via electron scattering
 - ^8B (NC NSI) via CEvNS
 - CNO (Solar metallicity) via Charge Current
