## Diffractive vector meson production

- Coherent diffraction: $\quad \frac{d \sigma^{\gamma^{*} p \rightarrow V_{p}}}{d t}=\frac{1}{16 \pi}\left|\left\langle A^{\gamma^{*} p \rightarrow V_{p}}\left(x_{p}, Q^{2}, \vec{\Delta}\right)\right\rangle\right|^{2}$

sensitive to the average size of the target
- Incoherent diffraction: $\left.\frac{d \sigma^{\gamma^{*} p \rightarrow V p^{*}}}{d t}=\frac{1}{16 \pi}\left(\left.\langle | A^{\gamma^{*} p \rightarrow V p}\left(x_{P}, Q^{2}, \vec{\Delta}\right)\right|^{2}\right\rangle-\left|\left\langle A^{\gamma^{*} p \rightarrow V p}\left(x_{P}, Q^{2}, \vec{\Delta}\right)\right\rangle\right|^{2}\right)$
sensitive to fluctuations (including geometric ones)

## Dipole picture: Scattering amplitude

H. Mäntysaari, B. Schenke, Phys. Rev. Lett. 117 (2016) 052301; Phys.Rev. D94 (2016) 034042

High energy factorization:

- $\gamma^{*} \rightarrow q \bar{q}: \psi^{\gamma}\left(r, Q^{2}, z\right)$
- $q \bar{q}$ dipole scatters with amplitude $N$
- $q \bar{q} \rightarrow V: \psi^{V}\left(r, Q^{2}, z\right)$

$$
A \sim \int d^{2} b d z d^{2} r \psi^{*} \psi^{V}\left(\vec{r}, z, Q^{2}\right) e^{-i \vec{b} \cdot \vec{\Delta}} N(\vec{r}, x, \vec{b})
$$

- Impact parameter $\boldsymbol{b}$ is the Fourier conjugate of transverse momentum transfer $\Delta \rightarrow$ Access to spatial structure $\left(t=-\Delta^{2}\right)$

## Color glass condensate formalism

H. Mäntysaari, B. Schenke, Phys. Rev. Lett. 117 (2016) 052301; Phys.Rev. D94 (2016) 034042

Compute the Wilson lines using color charges whose correlator depends on $\vec{b}_{\perp}$

$$
\left\langle\rho^{a}\left(\mathbf{b}_{\perp}\right) \rho^{b}\left(\mathbf{x}_{\perp}\right)\right\rangle=g^{2} \mu^{2}\left(x, \mathbf{b}_{\perp}\right) \delta^{a b} \delta^{(2)}\left(\mathbf{b}_{\perp}-\mathbf{x}_{\perp}\right)
$$

$$
N(\vec{r}, x, \vec{b})=N(\vec{x}-\vec{y}, x,(\vec{x}+\vec{y}) / 2)=1-\operatorname{Tr}\left(\mathrm{V}(\overrightarrow{\mathrm{x}}) \mathrm{V}^{\dagger}(\overrightarrow{\mathrm{y}})\right) / \mathrm{N}_{\mathrm{c}}
$$

The trace appears at the level of the amplitude, because we project on a color singlet

$$
A \sim \int d^{2} b d z d^{2} r \psi^{*} \psi^{V}\left(\vec{r}, z, Q^{2}\right) e^{-i \vec{b} \cdot \vec{\Delta}} N(\vec{r}, x, \vec{b})
$$

## Model impact parameter dependence (proton, nucleon)

H. Mäntysaari, B. Schenke, Phys. Rev. Lett. 117 (2016) 052301; Phys.Rev. D94 (2016) 034042

1) Assume Gaussian proton shape:

$$
T(\vec{b})=T_{\mathrm{p}}(\vec{b})=\frac{1}{2 \pi B_{\mathrm{p}}} e^{-b^{2} /\left(2 B_{\mathrm{p}}\right)}
$$

2) Assume Gaussian distributed and Gaussian shaped hot spots:

$$
P\left(b_{i}\right)=\frac{1}{2 \pi B_{\mathrm{qc}}} e^{-b_{i}^{2} /\left(2 B_{\mathrm{qc}}\right)} \text { (angles uniformly distributed) }
$$

$$
T_{\mathrm{p}}(\vec{b})=\frac{1}{N_{\mathrm{q}}} \sum_{i=1}^{N_{\mathrm{q}}} T_{\mathrm{q}}\left(\vec{b}-\vec{b}_{i}\right) \quad \text { with } N_{\mathrm{q}} \text { hot spots; } \quad T_{\mathrm{q}}(\vec{b})=\frac{1}{2 \pi B_{\mathrm{q}}} e^{-b^{2} /\left(2 B_{\mathrm{q}}\right)}
$$

## Diffractive $J / \psi$ production in e+p at HERA

Nucleon parameters $B_{q^{\prime}} B_{q c^{\prime}}$ can be constrained by e+p scattering data from HERA Exclusive diffractive $\mathrm{J} / \Psi$ production in $\mathrm{e}+\mathrm{p}$ : Incoherent $x$-sec sensitive to fluctuations

## JIMWLK evolution

How does energy evolution affect the nuclear structure?

B. Schenke, S. Schlichting, Phys.Rev.C 94 (2016) 4, 044907

## UPCs: $\gamma+\mathrm{Pb}$ measurement - Role of saturation effects

## H. Mäntysaari, F. Salazar, B. Schenke, Phys.Rev.D 106 (2022) 7, 074019

Here, ALICE removed interference and photon $k_{T}$ effects to get the $\gamma+\mathrm{Pb}$ cross section

ALICE Collaboration, Phys.Lett.B 817 (2021) 136280
Saturation effects improve agreement with experimental data significantly

## Saturation effects on nuclear geometry

H. Mäntysaari, F. Salazar, B. Schenke, Phys.Rev.D 106 (2022) 7, 074019

Fourier transform to coordinate space

JIMWLK evolution leads to growth of the nucleus towards small $x$ and depletion near the center (normalized so $\left.\int d^{2} b T_{A}(b)=208\right)$

## Effects of deformation on diffractive cross sections

H. Mäntysaari, B. Schenke, C. Shen, W. Zhao, arXiv:2303.04866

Implement deformation in the Woods-Saxon distribution:

$$
\rho(r, \Theta, \Phi) \propto \frac{1}{1+\exp ([r-R(\Theta, \Phi)] / a)}, R(\Theta, \Phi)=R_{0}\left[1+\underline{\beta_{2}}\left(\cos \gamma Y_{20}(\Theta)+\sin \gamma Y_{22}(\Theta, \Phi)\right)+\underline{\beta_{3}} Y_{30}(\Theta)+\underline{\beta_{4}} Y_{40}(\Theta)\right]
$$

Deformed nuclei exhibit larger fluctuation in the transverse projection:

## Effects of deformation on diffractive cross sections: Uranium

Deformation of the nucleus affects incoherent cross section at small $|t|$ (large length scales)

This observable provides direct information on the small $x$ structure

$$
Q^{2}=0
$$

## Effects of deformation on diffractive cross sections: Uranium

Deformation changes the shape of the average 2D projection of the nucleus
$\rightarrow$
Modification of the coherent cross section

## Effects of deformation on diffractive cross sections: Uranium

H. Mäntysaari, B. Schenke, C. Shen, W. Zhao, arXiv:2303.04866

$\cdot \beta_{2}, \beta_{3}$ and $\beta_{4}$ modify fluctuations at different length scales: Change incoherent cross section in different $|t|$ regions

## Towards smaller $x$

H. Mäntysaari, B. Schenke, C. Shen, W. Zhao, arXiv:2303.04866

- JIMWLK evolution to smaller $x$

-Both cross sections increase
-Ratio incoherent/coherent decreases because fluctuations are reduced (nucleus becomes smoother)
-Difference between different $\beta_{2}$ does not decrease noticeably in this $x$ range
- Is there a large enough $x$ range we can cover at the EIC ( at least $10^{-3}-10^{-2}$ )?

## Neon and Oxygen targets

H. Mäntysaari, B. Schenke, C. Shen, W. Zhao, arXiv:2303.04866

- ${ }^{20} \mathrm{Ne}$ has a bowling pin shape that leads to an increased incoherent cross section relative to an assumed spherical (on average) neon or a spherical oxygen

## ${ }^{20} \mathrm{Ne}$

PGCM: Projected Generator Coordinate Method: B. Bally et al., "Deciphering small system collectivity with bowling-pin-shaped ${ }^{20} \mathrm{Ne}$ isotopes," in preparation (2023); Mikael Frosini, Thomas Duguet, Jean-Paul Ebran, Benjamin Bally, Tobias Mongelli, Toma's R. Rodrıguez, Robert Roth, and Vittorio Soma, Eur. Phys. J. A 58, 63 (2022)

## Multi-scale sensitivity

## SUMMARY

- $|t|$-differential incoherent cross section is sensitive to fluctuations at different length scales: Effects of deformation, nucleon-, and sub-nucleon fluctuations
- This means:

1. Precision comparison of models to data requires taking deformation into account
2. Access to nuclear structure over 2 orders of magnitude in length scales!

- What we need:
- Separate incoherent from coherent in forward direction
- Detect leptons between from mid rapidity to backward rapidity (cover some $x$ range); or study other vector mesons (like $\rho$ and detect pions)

## BACKUP

## Good-Walker/Miettinen-Pumplin

Discussing mainly diffractive scattering in p+p collisions, Miettinen and Pumplin ask two questions:

1. What are the states which diagonalize the diffractive part of the S-matrix, so that their interactions are described simply by absorption coefficients?

Answer in their paper: States of the parton model (fixed number $N$, positions $\vec{b}_{i}$, fixed $x$ )
2. What causes the large variations in the absorption coefficients at a given impact parameter, which are implied by the large cross section for diffractive production?

Answer in their paper: Fluctuations in $N, \vec{b}_{i}, x$ between the states. "Among the parton states which describe a high-energy hadron, there are some which are rich in wee partons, and are therefore likely to interact, while other states have few or no wee partons, and correspond to the transparent channels of diffraction."

## Miettinen-Pumplin: Optical Model Formulation

H. I. Miettinen and J. Pumplin, Phys. Rev. D18 (1978) 1696

Target: Average optical potential
Beam particle: $|B\rangle=\sum_{k} C_{k}\left|\psi_{k}\right\rangle$ (linear combination of the eigenstates of diffraction $\left|\psi_{k}\right\rangle$ )
With $\operatorname{Im} T=1-\operatorname{Re} S$ the imaginary part of the scattering amplitude operator, we have
$\operatorname{Im} T\left|\psi_{k}\right\rangle=t_{k}\left|\psi_{k}\right\rangle$
with $t_{k}$ the probability for eigenstate $\left|\psi_{k}\right\rangle$ to interact with the target (absorption coefficients)
Normalize: $\langle B \mid B\rangle=\sum_{k}\left|C_{k}\right|^{2}=1$
Elastic scattering: $\langle B| \operatorname{Im} T|B\rangle=\sum_{k}\left|C_{k}\right|^{2} t_{k}=\langle t\rangle$

## Miettinen-Pumplin: Cross Sections

H. I. Miettinen and J. Pumplin, Phys. Rev. D18 (1978) 1696

Total cross section:
$d \sigma_{\mathrm{tot}} / d^{2} \vec{b}=2\langle t\rangle$
Elastic cross section:
$d \sigma_{\mathrm{el}} / d^{2} \vec{b}=\langle t\rangle^{2}$
Incoherent diffractive cross section:

$$
\begin{aligned}
& \left.d \sigma_{\mathrm{diff}} / d^{2} \vec{b}=\sum_{k}\left|\left\langle\psi_{k}\right| \operatorname{Im} T\right| B\right\rangle\left.\right|^{2}-d \sigma_{\mathrm{el}} / d^{2} \vec{b}=\left.\sum_{k}\left|\left\langle\psi_{k}\right| \operatorname{Im} T\right| \sum_{i} C_{i}\left|\psi_{i}\right\rangle\right|^{2}-d \sigma_{\mathrm{el}} / d^{2} \vec{b} \\
& \left.=\sum_{k, i}\left|\left\langle\psi_{k}\right| C_{i} t_{i}\right| \psi_{i}\right\rangle\left.\right|^{2}-d \sigma_{\mathrm{el}} / d^{2} \vec{b}=\sum_{k, i} \delta_{i k}\left|C_{i} t_{i}\right|^{2}-d \sigma_{\mathrm{el}} / d^{2} \vec{b}=\sum_{k}\left|C_{k}\right|^{2} t_{k}^{2}-\langle t\rangle^{2}=\left\langle t^{2}\right\rangle-\langle t\rangle^{2} \\
& d \sigma_{\text {diff }} / d^{2} \vec{b}=\left\langle t^{2}\right\rangle-\langle t\rangle^{2}
\end{aligned}
$$

## Color Glass Condensate calculation

-We study diffractive production in e+p/A (not p+p)
-The projectile can be understood as a quark anti-quark dipole (splitting from the incoming virtual photon)
-The fluctuations are included in the target wave function: Fluctuating spatial distribution of the gluon fields (normalization fluctuations correspond to $N$ fluctuations, spatial fluctuations to $\vec{b}_{i}$ fluctuations (see Blaizot and Traini, 2209.15545 [hep-ph] for the effect of fluctuations of the dipole size)

## Fluctuations in the target

Define
$\hat{T}_{p}(\vec{b})=\sum_{i}^{N_{q}} T_{G}\left(\vec{b}_{i}-\vec{b}\right)=\int d^{2} \vec{x} \hat{\rho}(\vec{x}) T_{G}(\vec{x}-\vec{b}) \quad T_{G}$ is the gluon distribution in a hot spot
$\hat{\rho}(\vec{x})=\sum_{i}^{N_{q}} \delta\left(\vec{x}-\vec{b}_{i}\right)$ is the hot spot density operator in the transverse plane
The dipole cross section can be written as
$N=\exp \left[-\frac{1}{2} \sigma_{\text {dip }}(x, \vec{r}) \hat{T}_{p}(\vec{b})\right] \approx 1-\frac{1}{2} \sigma_{\text {dip }}(x, \vec{r}) \hat{T}_{p}(\vec{b})$ in the weak field limit
The dipole cross section then is $\frac{d \sigma_{q \bar{q}}}{d^{2} \vec{b}}=2[1-N]=\sigma_{\mathrm{dip}}(x, \vec{r}) \hat{T}_{p}(\vec{b})$

## Fluctuations in the target

The dipole cross section then is $\frac{d \sigma_{q \bar{q}}}{d^{2} \vec{b}}=2[1-N]=\sigma_{\text {dip }}(x, \vec{r}) \hat{T}_{p}(\vec{b})$
This operator is diagonal in the basis of states $\left|\vec{b}_{1}, \ldots, \vec{b}_{N_{q}}\right\rangle$, where the $\vec{b}_{i}$ are the positions of the individual hot spots, frozen during the collision process:
These states can be considered the diffractive eigenstates
Coherent diffractive cross section:

$$
\int d^{2} \vec{b} d^{2} \vec{b}^{\prime} e^{-i \vec{\Delta} \cdot\left(\vec{b}-\vec{b}^{\prime}\right)}\left\langle\frac{d \sigma^{q \bar{q}}}{d^{2} \vec{b}}\right\rangle\left\langle\frac{d \sigma^{q \bar{q}}}{d^{2} \vec{b}^{\prime}}\right\rangle=\left\langle\Sigma_{q \bar{q}}(\vec{\Delta})\right\rangle^{2}
$$

with $\Sigma_{q \bar{q}}(\vec{\Delta})=\int d^{2} \vec{b} e^{-i \vec{\Delta} \cdot \vec{b}} \frac{d \sigma^{q \bar{q}}}{d^{2} \vec{b}}$ and $\langle\cdot\rangle$ is the average over the ground state wave function

## Fluctuations in the target

Total diffractive cross section:
Allow all possible diffractive eigenstates $|\alpha\rangle$ as intermediate states (assume dilute limit here)
$\left.\int d^{2} \vec{b} d^{2} \vec{b}^{\prime} e^{-i \vec{\Delta} \cdot\left(\vec{b}-\vec{b}^{\prime}\right)} \sigma_{\mathrm{dip}}^{2} \sum_{\alpha}\left|\langle\alpha| \hat{T}_{p}(\vec{b})\right| \psi_{0}\right\rangle\left.\right|^{2}=\left\langle\Sigma_{q \bar{q}}^{2}(\vec{\Delta})\right\rangle$
in analogy to the optical model example
This also shows the relation to the density-density correlation function $\left\langle\hat{T}_{p}(\vec{b}) \hat{T}_{p}\left(\vec{b}^{\prime}\right)\right\rangle$ and how we are sensitive to different distance scales via $\vec{b}-\vec{b}^{\prime}$

See Blaizot and Traini, 2209.15545 [hep-ph] for a more detailed discussion

## The scenario: Hadron moving at high momentum

Probe hadron (or nucleus) moving with large $P^{+}$at scale $x_{0} P^{+}$with $x_{0} \ll 1$
Separate partonic content based on longitudinal momentum $k^{+}=x P^{+}$
Large $x>x_{0}$ : Static and localized color sources $\rho$

## Dynamic color fields

The moving color sources generate a current, independent of light cone time $z^{+}$:

$$
J^{\mu, a}(z)=\delta^{\mu+} \rho^{a}\left(z^{-}, z_{T}\right) \quad a \text { is the color index of the gluon }
$$

This current generates delocalized dynamical fields $A^{\mu, a}(z)$ described by the Yang-Mills equations

$$
\begin{gathered}
{\left[D_{\mu}, F^{\mu \nu}\right]=J^{\nu}} \\
\text { with } D_{\mu}=\partial_{\mu}+i g A_{\mu} \text { and } F_{\mu \nu}=\frac{1}{i g}\left[D_{\mu}, D_{\nu}\right]=\partial_{\mu} A_{\nu}-\partial_{\nu} A_{\mu}+i g\left[A_{\mu}, A_{\nu}\right]
\end{gathered}
$$

These fields $A$ are the small $x<x_{0}$ degrees of freedom
They can be treated classically, because their occupation number is large $\langle A A\rangle \sim 1 / \alpha_{s}$

## Color Glass Condensate (CGC): Sources and fields

When $x \lesssim x_{0}$ the path integral $\langle\mathcal{O}\rangle_{\rho}$ is dominated by classical solution and we are done For smaller $x$ we need to do quantum evolution

## Wilson lines

Interaction of high energy color-charged probe with large $k^{-}$momentum (and small $k^{+}=\frac{k_{T}^{2}}{2 k^{-}}$) with the classical field of a nucleus can be described in the eikonal approximation:

The scattering rotates the color, but keeps $k^{-}$, transverse position $\vec{x}_{T}$, and any other quantum numbers the same.

The color rotation is encoded in a light-like Wilson line, which for a quark probe reads

$$
V_{i j}\left(\vec{x}_{T}\right)=\mathscr{P}\left(i g \int_{-\infty}^{\infty} A^{+, c}\left(z^{-}, \vec{x}_{T}\right) t_{i j}^{c} d z^{-}\right)
$$

## JIMWLK evolution

LO Small-x evolution resums logarithmically enhanced terms $\sim \alpha_{s} \ln \left(x_{0} / x\right)$

$$
\frac{d W_{x}[\rho]}{d \ln (1 / x)}=-\mathscr{H}_{\mathrm{JIMWLK}} W_{x}[\rho]
$$

Physically, one absorbs the quantum fluctuations in the interval $\left[x_{0}-d x, x_{0}\right]$ into stochastic fluctuations of the color sources by redefining the color sources $\rho$

## JIMWLK evolution

LO Small-x evolution resums logarithmically enhanced terms $\sim \alpha_{s} \ln \left(x_{0} / x\right)$

$$
\frac{d W_{x}[\rho]}{d \ln (1 / x)}=-\mathscr{H}_{\mathrm{JIMWLK}} W_{x}[\rho]
$$

Physically, one absorbs the quantum fluctuations in the interval $\left[x_{0}-d x, x_{0}\right]$ into stochastic fluctuations of the color sources by redefining the color sources $\rho$

Evolution is done using the Langevin formulation of the JIMWLK equations on the level of Wilson lines
K. Rummukainen and H. Weigert Nucl. Phys. A739 (2004) 183; T. Lappi, H. Mäntysaari, Eur. Phys. J. C73 (2013) 2307

Long distance tales are tamed by imposing a regulator in the JIMWLK kernel, $m$
S. Schlichting, B. Schenke, Phys.Lett. B739 (2014) 313-319

## Connection between the initial state of heavy ion collisions and the EIC

- These Wilson lines are the building blocks of the CGC
- In heavy ion collisions, one can compute the initial state by determining Wilson lines after the collision from the Wilson lines of the colliding nuclei
- At the EIC (and HERA, and in UPCs), cross sections will be calculated as convolutions of Wilson line correlators with perturbatively calculable and process-dependent impact factors
- This allows the computation of rather direct constraints for the initial state of heavy ion collisions from electron-nucleus ( $\gamma$-nucleus) or electron-proton collisions

## Heavy ion collision

Compute gluon fields after the collision using light cone gauge:
$A^{+}=0$ for a right moving nucleus, $A^{-}=0$ for a left moving nucleus
gauge transformation: $\quad A_{\mu}(x) \rightarrow V(x)\left(A_{\mu}(x)-\frac{i}{g} \partial_{\mu}\right) V^{\dagger}(x)$

using our Wilson lines $V^{\dagger}\left(x^{-}, \mathbf{x}_{\perp}\right)=\mathscr{P} \exp \left(-i g \int_{-\infty}^{x^{-}} d z^{-} A^{+}\left(z^{-}, \mathbf{x}_{\perp}\right)\right)$ (for the right moving nucleus)
Then, the gauge fields read (choosing $A^{\mu}=0$ for the quadrant for $x^{-}<0$ and $x^{+}<0$ )

$$
\begin{aligned}
& A^{i}(x)=\theta\left(x^{+}\right) \theta\left(x^{-}\right) \alpha^{i}\left(\tau, \mathbf{x}_{\perp}\right)+\theta\left(x^{-}\right) \theta\left(-x^{+}\right) \alpha_{P}^{i}\left(\mathbf{x}_{\perp}\right)+\theta\left(x^{+}\right) \theta\left(-x^{-}\right) \alpha_{T}^{i}\left(\mathbf{x}_{\perp}\right) \\
& A^{\eta}(x)=\theta\left(x^{+}\right) \theta\left(x^{-}\right) \alpha^{\eta}\left(\tau, \mathbf{x}_{\perp}\right) \quad \text { with } \alpha_{P}^{i}\left(\mathbf{x}_{\perp}\right)=\frac{1}{i g} V_{P}\left(\mathbf{x}_{\perp}\right) \partial^{i} V_{P}^{\dagger}\left(\mathbf{x}_{\perp}\right) \text { and } \alpha_{T}^{i}\left(\mathbf{x}_{\perp}\right)=\frac{1}{i g} V_{T}\left(\mathbf{x}_{\perp}\right) \partial^{i} V_{T}^{\dagger}\left(\mathbf{x}_{\perp}\right)
\end{aligned}
$$

$$
A^{\tau}=0, \text { because we chose Fock-Schwinger gauge } x^{+} A^{-}+x^{-} A^{+}=0
$$

## Heavy ion collision

Plugging this ansatz

$$
\begin{aligned}
A^{i}(x) & =\theta\left(x^{+}\right) \theta\left(x^{-}\right) \alpha^{i}\left(\tau, \mathbf{x}_{\perp}\right)+\theta\left(x^{-}\right) \theta\left(-x^{+}\right) \alpha_{P}^{i}\left(\mathbf{x}_{\perp}\right)+\theta\left(x^{+}\right) \theta\left(-x^{-}\right) \alpha_{T}^{i}\left(\mathbf{x}_{\perp}\right) \\
A^{\eta}(x) & =\theta\left(x^{+}\right) \theta\left(x^{-}\right) \alpha^{\eta}\left(\tau, \mathbf{x}_{\perp}\right)
\end{aligned}
$$

into YM equations leads to singular terms on the boundary from derivatives of $\theta$-functions
Requiring that the singularities vanish leads to the solutions

$$
\alpha^{i}=\alpha_{P}^{i}+\alpha_{T}^{i} \quad \alpha^{\eta}=-\frac{i g}{2}\left[\alpha_{P j}, \alpha_{T}^{j}\right] \quad \begin{aligned}
& \partial_{\tau} \alpha^{i}=0 \\
& \partial_{\tau} \alpha^{\eta}=0
\end{aligned}
$$

These are the gauge fields in the forward light cone.
We can compute $T^{\mu \nu}$ from it, providing an initial condition for hydrodynamics.

## Geometry, fluctuations, ...

- All the information on geometry and nucleon and sub-nucleon fluctuations is contained in the distribution of color charges $\rho_{P / T}^{a}\left(x^{\mp}, \mathbf{x}_{\perp}\right)$
- Typically, use the MV model, which gives $\left\langle\rho^{a}\left(\mathbf{b}_{\perp}\right) \rho^{b}\left(\mathbf{x}_{\perp}\right)\right\rangle=g^{2} \mu^{2}\left(x, \mathbf{b}_{\perp}\right) \delta^{a b} \delta^{(2)}\left(\mathbf{b}_{\perp}-\mathbf{x}_{\perp}\right)$
- The color charge distribution $g^{2} \mu\left(x, \mathbf{b}_{\perp}\right)$ depends on the longitudinal momentum fraction $x$ and the transverse position $\mathbf{b}_{\perp}$. The latter needs to be modeled, the former can be modeled or obtained from e.g. JIMWLK evolution
- We factorize $\mu\left(x, \mathbf{b}_{\perp}\right) \sim T\left(\mathbf{b}_{\perp}\right) \mu(x)$ and constrain the impact parameter $\mathbf{b}_{\perp}$ dependence using input from a process sensitive to geometry, such as diffractive VM production
- The cross section for that process can be expressed with the Wilson lines of the target The same quantities we have used to initialize the heavy ion collision

## Color sources

How localized are these sources? $\Delta z^{-} \sim \frac{1}{k^{+}}=\frac{1}{x P^{+}}$
What is the resolution scale of the probe? $\frac{1}{x_{0} P^{+}}>\frac{1}{x P^{+}}$for $x>x_{0}$
$\rightarrow$ Color sources look fully localized to the probe in $z^{-}$

## Color sources

How fast do they evolve? $\Delta z^{+} \sim \frac{1}{k^{-}}=\frac{2 k^{+}}{k_{T}^{2}}=\frac{2 x P^{+}}{k_{T}^{2}}\left(\right.$ because $\left.a_{\mu} b^{\mu}=a^{+} b^{-}+a^{-} b^{+}-\vec{a}_{T} \cdot \vec{b}_{T}\right)$
What is the time scale of the probe? $\tau \approx \frac{2 x_{0} P^{+}}{k_{T}^{2}}<\frac{2 x P^{+}}{k_{T}^{2}}$
$\rightarrow$ Color sources look static to the probe in light cone time $z^{+}$

## Predictions for e-Au at the future EIC

DVCS and exclusive $J / \psi$ : Spectra and azimuthal modulations

Characteristic dips in spectra due to Woods-Saxon nuclear profile Azimuthal modulations $v_{n}$ a few percent for DVCS, and less than $1 \%$ for $J / \psi$

## Predictions for e-Au at the future EIC

Nuclear suppressions factor for DVCS and exclusive $J / \psi$

$$
R_{e A}=\left.\frac{\mathrm{d} \sigma^{e+A \rightarrow e+A+V} / \mathrm{d} t \mathrm{~d} Q^{2} \mathrm{~d} x_{\mathbb{P}}}{A^{2} \mathrm{~d} \sigma^{e+p \rightarrow e+p+V} / \mathrm{d} t \mathrm{~d} Q^{2} \mathrm{~d} x_{\mathbb{P}}}\right|_{t=0}
$$

Expect $R_{e A}=1$ in the dilute limit. Mäntysaari, Venugopalan. 1712.02508

Significant suppression that evolves with energy/ $x_{\mathbb{P}}$

Larger suppression for DVCS due to larger dipole contributions.

## e+0: Oxygen wave function dependence

oxygen

## Light cone

Light cone coordinates $\quad v^{ \pm}=\left(v^{0} \pm v^{3}\right) / \sqrt{2}$
In the future light cone define $x^{+}=\frac{\tau}{\sqrt{2}} e^{+\eta}$, and $x^{-}=\frac{\tau}{\sqrt{2}} e^{-\eta}$
or inverted $\tau=\sqrt{2 x^{+} x^{-}}$, and $\eta=\frac{1}{2} \ln \left(\frac{x^{+}}{x^{-}}\right)_{45}$

## Weight functional

What is the weight functional?

Need to model. E.g. the McLerran-Venugopalan model:
Assume a large nucleus, invoke central limit theorem. All correlations of $\rho^{a}$ are Gaussian $W_{x_{0}}[\rho]=\mathscr{N} \exp \left(-\frac{1}{2} \int d x^{-} d^{2} x_{T} \frac{\rho^{a}\left(x^{-}, x_{T}\right) \rho^{a}\left(x^{-}, x_{T}\right)}{\lambda_{x_{0}}\left(x^{-}\right)}\right)$
where $\lambda_{x_{0}}\left(x^{-}\right)$is related to the transverse color charge density distribution of the nucleus

## Weight functional

...where $\lambda_{x_{0}}\left(x^{-}\right)$is related to the transverse color charge density distribution of the nucleus

$$
\mu^{2}=\int d x^{-} \lambda_{x_{0}}\left(x^{-}\right)=\frac{\left(g^{2} C_{F}\right)\left(A N_{c}\right)}{\pi R_{A}^{2}} \frac{1}{N_{c}^{2}-1}=\frac{g^{2} A}{2 \pi R_{A}^{2}} \sim A^{1 / 3}
$$

That color charge density is related to $Q_{s}$, the saturation scale.
normalized per color degree of freedom

## Towards smaller $x$ : Do deformation effects survive?

H. Mäntysaari, B. Schenke, C. Shen, W. Zhao, in progress

Some changes in the cross section, but deformation effects survive

## Towards smaller $x$ : Incoherent / coherent ratio

H. Mäntysaari, B. Schenke, C. Shen, W. Zhao, in progress

- Both cross sections grow for decreasing $x$
- Because fluctuations are reduced, incoherent/coherent ratio decreases
- Effects of deformation not noticeably reduced

## Comparing Neon and oxygen

H. Mäntysaari, B. Schenke, C. Shen, W. Zhao, in progress

- Incoherent cross section at small $|\mathrm{t}|$ captures the deformation of ${ }^{20} \mathrm{Ne}$
- Significant difference between ${ }^{20} \mathrm{Ne}$ and ${ }^{16} \mathrm{O}$ diffractive cross sections

## Neon - JIMWLK evolution

G. Giacalone, B. Schenke, S. Schlichting, P. Singh, in progress

- Small-x evolution does not melt the bowling pin shape

## Neon+Neon collisions - JIMWLK evolution

G. Giacalone, B. Schenke, S. Schlichting, P. Singh, in progress

- After the collision at different energies $(x)$, measure the spatial eccentricities

- Expected reduction - smoother distributions, but no large change

## Isobar shapes - JIMWLK evolution

G. Giacalone, B. Schenke, S. Schlichting, P. Singh, in progress
