Summary

Dec 1930: Wolfgang Pauli's letter to physicists at a workshop in Tübingen:

Wolfgang Pauli

Dear Radioactive Ladies and Gentlemen,

....., I have hit upon a desperate remedy to save the "exchange theorem" of statistics and the law of conservation of energy. Namely, the possibility that there could exist in the nuclei electrically neutral particles, that I wish to call neutrons.... The mass of the neutrons should be of the same order of magnitude as the electron mass and in any event not larger than 0.01 proton masses. The continuous beta spectrum would then become understandable by the assumption that in beta decay a neutron is emitted in addition to the electron such that the sum of the energies of the neutron and the electron is constant.....

Unfortunately, I cannot appear in Tübingen personally since I am indispensable here in Zurich because of a ball on the night of 6/7 December. With my best regards to you, and also to Mr Back.

Your humble servant

. W. Pauli

Offener Brief an die Gruppe der Radioaktiven bei der
Genvereins-Tagung in Tübingen.

Abeschrift

Physikalisches Institut
der Eidg. Technischen Hochschule
Zürich

Zürich, d. 26. 1930
Oloriastrasse

Liebe Radioaktive Damen und Herren,

Wie der Überbringer dieser Zeilen, den ich halbwitlig anzufragen bitte, Ihnen das näheres auseinandersetzen wird, bin ich angelegte der "falschen" Statistik der β - und β -Kerne, sowie des kontinuierlichen β -Spektrums auf einen verwerflichen Ausweg verfallen um den "Mischelast" (1) der Statistik und den Energiemass zu retten. Nämlich die Möglichkeit, es könnten elektrisch neutrale Teilchen, die ich Neutronen nennen will, in den Kernen existieren, welche den Spin $1/2$ haben und das Ausschliessungsprinzip befolgen und sich von Lichtquanten ausserdem noch dadurch unterscheiden, dass sie nicht mit Lichtgeschwindigkeit laufen. Die Masse der Neutronen müsste von derselben Grössenordnung wie die Elektronenmasse sein und jedenfalls nicht grösser als 0,01 Protonenmasse. Das kontinuierliche β -Spektrum wäre dann verständlich unter der Annahme, dass beim β -Zerfall mit dem Elektron jeweils noch ein Neutron emittiert wird, dazwischen, dass die Summe der Energien von Neutron und Elektron konstant ist.

Man handelt es sich weiter darum, welche Kräfte auf die Neutronen wirken. Das wahrscheinlichste Modell für das Neutron scheint mir aus wellenmechanischen Gründen (näheres weiss der Überbringer dieser Zeilen) dieses zu sein, dass das ruhende Neutron ein magnetischer Dipol von einem gewissen Moment μ ist. Die Experimente verlaufen wohl, dass die ionisierende Wirkung eines solchen Neutrons nicht grösser sein kann, als die eines gamma-Strahls und darf dann μ wohl nicht grösser sein als $e \cdot (10^{-33} \text{ cm})$.

Ich traue mich vorläufig aber nicht, etwas über diese Idee zu publizieren und wende mich erst vertrauensvoll an Sie, liebe Radioaktive, mit der Frage, wie es um den experimentellen Nachweis eines solchen Neutrons stünde, wenn es sich ebenwies oder eben lokal grössere Durchdringungsvorgänge besitzen würde, wie ein gamma-Strahl.

Ich gebe zu, dass mein Ausweg vielleicht von vornherein wenig wahrscheinlich erscheinen wird, weil man die Neutronen, wenn sie existieren, wohl schon längst gesehen hätte. Aber mir war wagt, gewagt und der Ernst der Situation beim kontinuierlichen β -Spektrum wird durch einen Ausbruch meines verehrten Vorgängers in Amst, Herrn Debye, beleuchtet, der mir kürzlich in Basel gesagt hat: "O, daran soll man es besten gar nicht denken, sowie es die neuen Steuern." Darum soll man jeden Weg zur Rettung ernstlich diskutieren. Also, liebe Radioaktive, prüfet, und richtet. Leider kann ich nicht persönlich in Tübingen erscheinen, da ich infolge eines in der Nacht vom 6. zum 7. Dez. in Zürich stattfindenden Balles hier unabweislich bin. Mit vielen Grüssen an Sie, sowie an Herrn Back, hier unterfertigter Diener

Summary

1950's: Fred Reines at Los Alamos and Clyde Cowan use the Hanford nuclear reactor (1953) and the new Savannah River nuclear reactor (1955) to find neutrinos. A detector filled with **water with CdCl₂ in solution** was located 11 meters from the reactor center and 12 meters underground.

The detection sequence was as follows:

- 1 $\bar{\nu}_e + p \rightarrow n + e^+$
- 2 $e^+ + e^- \rightarrow \gamma\gamma$
- 3 $n + {}^{108}\text{Cd} \rightarrow {}^{109}\text{Cd}^* \rightarrow {}^{109}\text{Cd} + \gamma (\tau = 5\mu\text{s}).$

Neutrinos first detected using a nuclear reactor!

Reines shared 1995 Nobel for work on neutrino physics.

Summary

Classification of "Events"	
<u>Single Tracks</u>	
$E_{\mu} < 300 \text{ MeV}/c^2$ ^a	48
$E_{\mu} > 300$	34
> 400	19
> 500	8
> 600	3
> 700	2
Total "single track events"	34
<u>Vertex Events</u>	
Visible Energy Released < 1 BeV	10
Visible Energy Released > 1 BeV	7
Total vertex events	22
<u>"Shower" Events</u>	
Energy of "electron" = 200 ± 100 MeV	3
220	1
240	1
280	2
Total "shower events" ^b	6

^a These are not included in the "event" count.

^b The two shower events which are so located that their potential energy release in the chamber corresponds to masses of less than 300 MeV/c are not included here.

Result: 40 neutrino interactions recorded in the detector, 6 of the resultant particles were identified as background and 34 identified as $\mu \Rightarrow \nu_x = \nu_{\mu}$

The first successful accelerator neutrino experiment was at Brookhaven Lab. 1998 NOBEL PRIZE

1980's - 90's: The number of neutrino types is precisely determined from studies of Z^0 boson properties produced in e^+e^- colliders.

1983: CERN W W boson
1983: CERN Z Z boson

1957,1967: B. Pontecorvo proposes that neutrinos of a particular flavor are a mix of quantum states with different masses:

$$\begin{pmatrix} \nu_a \\ \nu_b \end{pmatrix} = \begin{pmatrix} \cos(\theta) & \sin(\theta) \\ -\sin(\theta) & \cos(\theta) \end{pmatrix} \begin{pmatrix} \nu_1 \\ \nu_2 \end{pmatrix}$$

$$\nu_a(t) = \cos(\theta)\nu_1(t) + \sin(\theta)\nu_2(t)$$

$$\begin{aligned} P(\nu_a \rightarrow \nu_b) &= |\langle \nu_b | \nu_a(t) \rangle|^2 \\ &= \sin^2(\theta) \cos^2(\theta) |e^{-iE_2 t} - e^{-iE_1 t}|^2 \end{aligned}$$

$$P(\nu_a \rightarrow \nu_b) = \sin^2 2\theta \sin^2 \frac{1.27 \Delta m_{21}^2 L}{E} \quad \text{where}$$

$\Delta m_{21}^2 = (m_2^2 - m_1^2)$ in eV^2 , L (km) and E (GeV).

At the 1st maximum of appearance $\Delta m^2 = \frac{\pi}{2} \frac{1}{1.27} \left(\frac{E}{L}\right) \max 1$

Observation of oscillations implies non-zero mass states

1967: **Ray Davis** from BNL installs a large detector, containing 615 tons of tetrachloroethylene (cleaning fluid), 1.5km underground (4850 ft) in Homestake mine, SD.

- $\nu_e^{\text{sun}} + {}^{37}\text{Cl} \rightarrow e^- + {}^{37}\text{Ar}$, $\tau({}^{37}\text{Ar}) = 35$ days.
- Number of Ar atoms \approx number of ν_e^{sun} interactions.

Results: 1969 - 1993 Measured 2.5 ± 0.2 ^{Ray Davis} SNU (1 SNU = 1 neutrino interaction per second for 10^{36} target atoms) while theory predicts 8 SNU. This is a ν_e^{sun} deficit of 69%.

\Rightarrow first experimental hint of oscillations

Summary

Charge-parity symmetry: laws of physics are the same if a particle is interchanged with its anti-particle and left and right are swapped.

A violation of CP \Rightarrow matter/anti-matter asymmetry.

In 3-flavor mixing the degree of CP violation is determined by the Jarlskog invariant:

$$J_{\text{CP}}^{\text{PMNS}} \equiv \underbrace{\frac{1}{8} \sin 2\theta_{12} \sin 2\theta_{13} \sin 2\theta_{23} \cos \theta_{13}}_{J_{\text{CP}}^{\text{max}}} \sin \delta_{\text{CP}}.$$

(JHEP 09 (2020) 178, arXiv:2007.14792)

Given the current best-fit values of the ν mixing angles :

$$J_{\text{CP}}^{\text{PMNS}} \approx 3 \times 10^{-2} \sin \delta_{\text{CP}}.$$

For CKM:

$$J_{\text{CP}}^{\text{CKM}} \approx 3 \times 10^{-5},$$

despite the large value of $\delta_{\text{CP}}^{\text{CKM}} \approx 70^\circ$.

Summary

1978 and 1986: L. Wolfenstein, S. Mikheyev and A. Smirnov propose the scattering of ν_e on electrons in matter acts as a refractive index \Rightarrow neutrinos in matter have different effective mass than in vacuum.

For $P_{\text{osc}} = P(\nu_\mu \rightarrow \nu_e)$:

We can determine the mass ordering ($m_3 > m_1$ or $m_1 > m_3$) of neutrinos using $\nu_\mu \rightarrow \nu_e$ oscillations over long distances in the earth.

$\nu_\mu \rightarrow \nu_e$ oscillations are sensitive to all mixing parameters contributing to the Jarlskog invariant. With terms up to second order in $\alpha \equiv \Delta m_{21}^2 / \Delta m_{31}^2 = 0.03$ and $\sin^2 \theta_{13} = 0.02$, (M. Freund. Phys. Rev. D 64, 053003):

$$P(\nu_\mu \rightarrow \nu_e) \cong P(\nu_e \rightarrow \nu_\mu) \cong \underbrace{P_0}_{\theta_{13}} + \underbrace{P_{\sin \delta}}_{\text{CP violating}} + \underbrace{P_{\cos \delta}}_{\text{CP conserving}} + \underbrace{P_3}_{\text{solar oscillation}}$$

for oscillations in vacuum: $\Delta = \Delta m_{31}^2 L / 4E$

$$P_0 = \sin^2 \theta_{23} \sin^2 2\theta_{13} \sin^2(\Delta),$$

$$P_{\sin \delta} = \alpha 8J_{\text{CP}} \sin^3(\Delta),$$

$$P_{\cos \delta} = \alpha 8J_{\text{CP}} \cot \delta_{\text{CP}} \cos \Delta \sin^2(\Delta),$$

$$P_3 = \alpha^2 \cos^2 \theta_{23} \sin^2 2\theta_{12} \sin^2(\Delta),$$

For $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$, $\underbrace{P_{\sin \delta} \rightarrow -P_{\sin \delta}}_{\text{CP asymmetry } (\delta \neq 0)}$

$\nu_\mu \rightarrow \nu_e$ oscillations are sensitive to all mixing parameters contributing to the Jarlskog invariant. With terms up to second order in $\alpha \equiv \Delta m_{21}^2/\Delta m_{31}^2 = 0.03$ and $\sin^2 \theta_{13} = 0.02$, (M. Freund. Phys. Rev. D 64, 053003):

$$P(\nu_\mu \rightarrow \nu_e) \cong P(\nu_e \rightarrow \nu_\mu) \cong \underbrace{P_0}_{\theta_{13}} + \underbrace{P_{\sin \delta}}_{\text{CP violating}} + \underbrace{P_{\cos \delta}}_{\text{CP conserving}} + \underbrace{P_3}_{\text{solar oscillation}}$$

for oscillations in matter with constant density: $\Delta = \Delta m_{31}^2 L/4E$, $A = \sqrt{2}G_F N_e 2E/\Delta m_{31}^2$

$$P_0 = \sin^2 \theta_{23} \frac{\sin^2 2\theta_{13}}{(A-1)^2} \sin^2[(A-1)\Delta],$$

$$P_{\sin \delta} = \alpha \frac{8J_{\text{CP}}}{A(1-A)} \sin \Delta \sin(A\Delta) \sin[(1-A)\Delta],$$

$$P_{\cos \delta} = \alpha \frac{8J_{\text{CP}} \cot \delta_{\text{CP}}}{A(1-A)} \cos \Delta \sin(A\Delta) \sin[(1-A)\Delta],$$

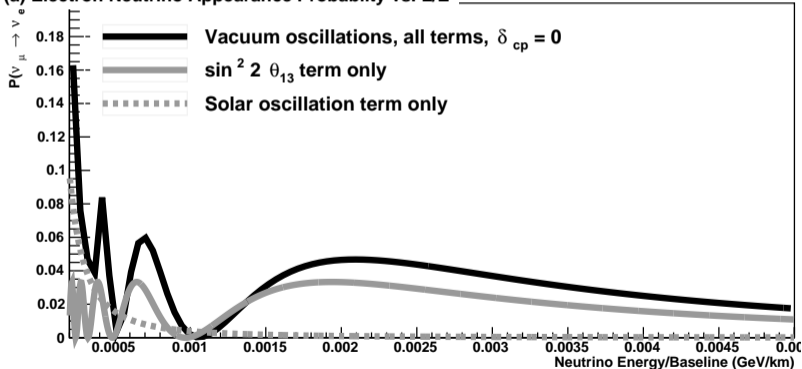

$$P_3 = \alpha^2 \cos^2 \theta_{23} \frac{\sin^2 2\theta_{12}}{A^2} \sin^2(A\Delta),$$

For $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$, $\underbrace{P_{\sin \delta} \rightarrow -P_{\sin \delta}}_{\text{CP asymmetry } (\delta \neq 0)}$, $\underbrace{A \rightarrow -A}_{\text{matter asymmetry}}$

The $\nu_\mu \rightarrow \nu_e$ probability maxima due to the atmospheric oscillation scale occur at

$$\frac{L_n \text{ (km)}}{E_n \text{ (GeV)}} = \left(\frac{\pi}{2} \right) \frac{(2n - 1)}{1.27 \times \Delta m_{31}^2 \text{ (eV}^2\text{)}} \approx (2n - 1) \times \frac{515 \text{ km}}{\text{GeV}}$$

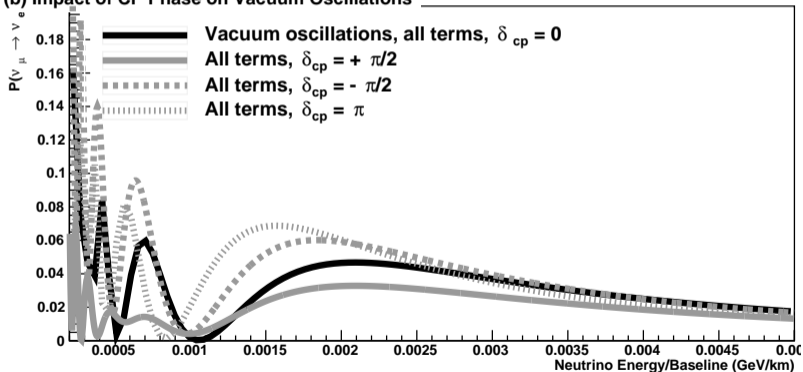

(a) Electron Neutrino Appearance Probability vs. L/E

The $\nu_\mu \rightarrow \nu_e$ probability maxima due to the atmospheric oscillation scale occur at

$$\frac{L_n \text{ (km)}}{E_n \text{ (GeV)}} = \left(\frac{\pi}{2} \right) \frac{(2n - 1)}{1.27 \times \Delta m_{31}^2 \text{ (eV}^2\text{)}} \approx (2n - 1) \times \frac{515 \text{ km}}{\text{GeV}}$$

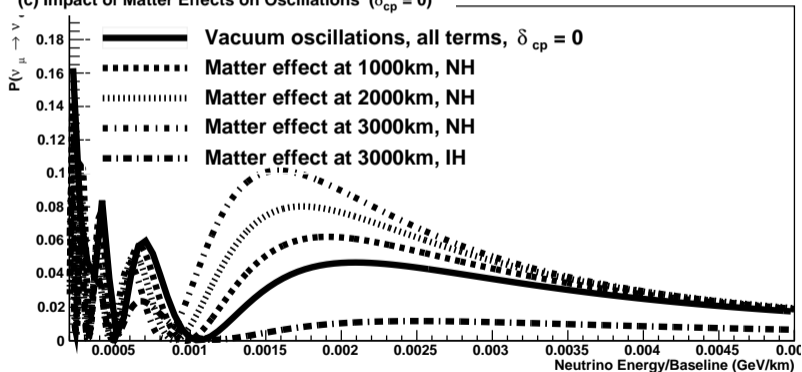

(b) Impact of CP Phase on Vacuum Oscillations

The $\nu_\mu \rightarrow \nu_e$ probability maxima due to the atmospheric oscillation scale occur at

$$\frac{L_n \text{ (km)}}{E_n \text{ (GeV)}} = \left(\frac{\pi}{2} \right) \frac{(2n-1)}{1.27 \times \Delta m_{31}^2 \text{ (eV}^2\text{)}} \approx (2n-1) \times \frac{515 \text{ km}}{\text{GeV}}$$

(c) Impact of Matter Effects on Oscillations ($\delta_{cp} = 0$)

The total number of electron neutrino appearance events expected for a given exposure from a muon neutrino source as a function of baseline is given as

$$N_{\nu_e}^{\text{appear}}(L) = N_{\text{target}} \int \Phi^{\nu_\mu}(E_\nu, L) \times P^{\nu_\mu \rightarrow \nu_e}(E_\nu, L) \times \sigma^{\nu_e}(E_\nu) dE_\nu$$

Assume the neutrino beam source produces a wide coverage that is flat in energy in the oscillation region and approximate the probability with the dominant term (no matter effect)

$$\begin{aligned} \Phi^{\nu_\mu}(E_\nu, L) &\approx \frac{C}{L^2}, \quad C = \text{number of } \nu_\mu / \text{m}^2 / \text{GeV} / \text{MW} / \text{yr at 1 km} \\ P^{\nu_\mu \rightarrow \nu_e}(E_\nu, L) &\approx \underbrace{\sin^2 \theta_{23} \sin^2 2\theta_{13} \sin^2(1.27 \Delta m_{31}^2 L / E_\nu)}_{P_0} \end{aligned}$$

$$\sigma^{\nu_e}(E_\nu) = 0.7 \times 10^{-42} (\text{m}^2 / \text{GeV} / \text{N}) \times E_\nu, \quad E_\nu > 1 \text{ GeV}$$

$$N_{\text{target}} = 6.022 \times 10^{32} \text{ N/kt}$$

Assuming constant flux: $C \approx 1.2 \times 10^{17} \nu_\mu / \text{m}^2 / \text{GeV} / (\text{MW} / \text{yr})$ at 1 km:

$$N_{\nu_e}^{\text{appear}}(L) \approx (2 \times 10^6 \text{ events} / (\text{kt} / \text{MW} / \text{yr})) (\text{km} / \text{GeV})^2 \times \int_{x_0}^{x_1} \frac{\sin^2(ax)}{x^3} dx, \quad x \equiv L / E_\nu, \quad a \equiv 1.27 \Delta m_{31}^2.$$

For $x_0 = 100 \text{ km/GeV}$ and $x_1 = 2000 \text{ km/GeV}$ (1st and 2nd oscillation maxima)

$N_{\nu_e}^{\text{appear}}(L) \sim \mathcal{O}(20) \text{ events} / (\text{kt} / \text{MW} / \text{yr})$ independent of baseline
Need massive detectors $\sim \mathcal{O}(100) \text{ kt}$ deep underground and MW beams to study oscillations

- Allowed regions from global fit 2020.
- Colored regions (black contour curves) are obtained without (with) the inclusion of the tabulated SK-atm χ^2 data.
- The different contours correspond to the two-dimensional allowed regions at 1σ , 90%, 2σ , 99%, 3σ CL (2 dof).
- Atmospheric mass splitting Δm_{31}^2 used for normal ordering (NO) and Δm_{32}^2 for inverted ordering (IO).

Summary

Due to the very small masses and large mixing of neutrinos, their oscillations over a long distance act as *an exquisitely precise interferometer with high sensitivity to very small perturbations (W. Marciano, BNL)* caused by new physics phenomena, such as:

- sterile neutrino states that mix with the three known active neutrino states
- nonstandard interactions in matter that manifest in long-baseline oscillations as deviations from the three-flavor mixing model
- new long-distance potentials arising from discrete symmetries that manifest as small perturbations on neutrino and antineutrino oscillations over a long baseline
- large compactified extra dimensions from String Theory models that manifest through mixing between the Kaluza-Klein states and the three active neutrino states

We need more guidance from theory

$$\Delta m_{41}^2 \sim 1 \text{ eV}^2$$

Summary

The charge-parity (CP) asymmetry is defined as

$$\mathcal{A}_{cp} = \frac{P(\nu_\mu \rightarrow \nu_e) - P(\bar{\nu}_\mu \rightarrow \bar{\nu}_e)}{P(\nu_\mu \rightarrow \nu_e) + P(\bar{\nu}_\mu \rightarrow \bar{\nu}_e)}$$

The integrated CP asymmetry at a baseline of 1300km (D. Dutta *et al.* JHEP 1511 (2015) 039):

Observation of a CP asymmetry is not sufficient to determine its origin.

- In the Standard Model,

$$\mathcal{L}_{CC} = (\bar{\ell}_\alpha \gamma^\mu P_L \nu_\alpha) (\bar{f} \gamma_\mu P_L f')$$

$$\mathcal{L}_{NC} = (\bar{\nu}_\alpha \gamma^\mu P_L \nu_\alpha) (\bar{f} \gamma_\mu P_L f')$$

- With new physics, we could have

$$\mathcal{L}_{CC} = (\bar{\ell}_\alpha \gamma^\mu P_L \nu_\beta) (\bar{f} \gamma_\mu P_{L,R} f')$$

CC NSI
production, detection

$$\mathcal{L}_{NC} = (\bar{\nu}_\alpha \gamma^\mu P_L \nu_\beta) (\bar{f} \gamma_\mu P_{L,R} f')$$

NC NSI
propagation

$$H = U \begin{pmatrix} 0 & & \\ & \Delta m_{21}^2/2E & \\ & & \Delta m_{31}^2/2E \end{pmatrix} U^\dagger + \tilde{V}_{\text{MSW}}$$

$$\tilde{V}_{\text{MSW}} = \sqrt{2} G_F N_e \begin{pmatrix} 1 + \epsilon_{ee}^m & \epsilon_{e\mu}^m & \epsilon_{e\tau}^m \\ \epsilon_{e\mu}^{m*} & \epsilon_{\mu\mu}^m & \epsilon_{\mu\tau}^m \\ \epsilon_{e\tau}^{m*} & \epsilon_{\mu\tau}^{m*} & \epsilon_{\tau\tau}^m \end{pmatrix}$$

Summary

NSI could also impact CPV interpretation in long-baseline

(M. Masud, A. Chatterjee, P. Mehta arXiv:1510.08261):

The Deep Underground Neutrino Experiment (DUNE) at the Long Baseline Neutrino Facility (LBNF)

The DUNE Experiment: A Neutrino Interferometer

- **A very long baseline experiment:** 1300km from Fermilab in Batavia, IL to the Sanford Underground Research Facility (former Homestake Mine) in Lead, SD.
- A highly capable near detector facility at Fermilab.
- Very deep (1 mile underground) far detectors: 4×10 -kiloton fiducial (17 kt total) **Liquid-Argon Time-Projection-Chambers** with state-of-the-art instrumentation.
- **High intensity tunable wide-band neutrino beam** produced from 120 GeV Main Injector proton accelerator at Fermilab upgraded to 2MW.

Highlights

Summary

A long-baseline neutrino oscillation experiment:

- precision measurements of the parameters that govern $\nu_{\mu} \rightarrow \nu_e$ oscillations; this includes precision measurement of the third mixing angle θ_{13} , measurement of the charge-parity (CP) violating phase δ_{CP} , and determination of the neutrino mass ordering (the sign of $\Delta m_{31}^2 = m_3^2 - m_1^2$), the so-called mass hierarchy
- precision measurements of the mixing angle θ_{23} , including the determination of the octant in which this angle lies.
- Searches for physics beyond the 3 flavor model using neutrino oscillations

Summary

A proton decay experiment:

A neutrino telescope:

A fixed target experiment:

- complementary searches for proton decay in several important candidate decay modes, e.g., $p \rightarrow K^+ \bar{\nu}$ as well as other baryon number violating signals.

- detection and measurement of the neutrino flux, spectrum and time evolution from a core-collapse supernova within our galaxy, should one occur during the lifetime of DUNE

- Unique searches for heavy neutral leptons, dark matter scattering, precision electroweak measurements, nuclear form factors and other measurements made possible by the high power proton beam and neutrino scattering in the near detector

The LBNF Phase I facility provides all infrastructure needed for full DUNE scope

**Project schedule:
Start of physics with far detector 1: 2029
Beamline comes online: 2031**

LBNF and DUNE were reconstituted in 2015 (CD1R) from the LBNE experiment as a staged program with the goal to reach CP violation sensitivity with a precision of 3σ for 75% of δ_{cp} values as specified by the 2014 P5 (Particle Physics Project Prioritization Panel)

DUNE Phase I detectors

- 2 FD modules: FD1 “horizontal drift” and FD 2 “vertical drift” LArTPCs
- ND LArTPC detector+ muon spectrometer + off-axis system
- SAND magnetized low density tracker on-axis near detector for neutrino flux measurements

Phase I FDs are currently under construction and contributions detailed in DUNE multilateral MOU (signed by DOE, UK, France, Italy, Brazil and CERN on Nov 17, 2023).

ND LAr, TMS and SAND straw-tube tracker prototyping underway

Accelerator Complex Evolution (ACE): 2023 FNAL plan to deliver 1.7-2.1 MW by start of Phase I

LBNF and DUNE were reconstituted in 2015 (CD1R) from the LBNE experiment as a staged program with the goal to reach CP violation sensitivity with a precision of 3σ for 75% of δ_{cp} values as specified by the 2014 P5 (Particle Physics Project Prioritization Panel)

DUNE Phase II detectors

- **Baseline is two additional “vertical drift” LArTPCs which meets all physics goals. R&D ongoing on options to enhance DUNE physics capabilities. Non LArTPC options for FD4 could be considered if performance and timeline requirements of DUNE are met.**
- **More Capable Near Detector (MCND) to ensure completion of the DUNE physics program and open up opportunities for new BSM physics searches.**

US presented plans for LBNF/DUNE Phase II to 2023 P5 planning effort - report to be presented publicly on Dec 7-8, 2023

North Detector Cavern

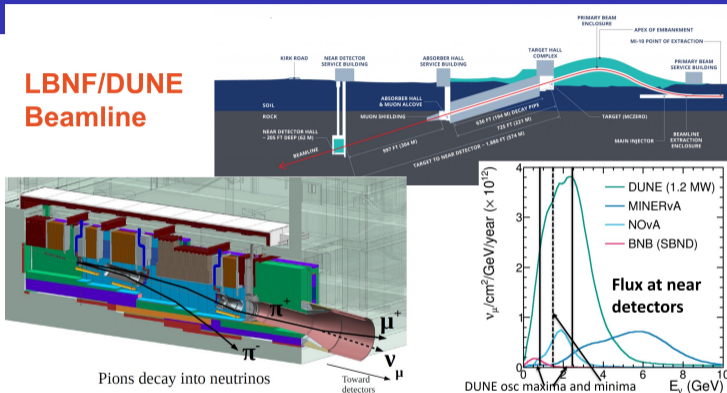

Worker, for scale

North Cavern – midpoint looking west

Performing geological survey

LBNF/DUNE Beamline

- Primary proton beam 60-120 GeV with initial 1.2 MW beam power (Phase I), upgradable to 2.4 MW (Phase II). Embankment allows target complex to be at grade (BNL concept)
- Wide-band beam (on-axis) optimized for CP violation sensitivity - uses 3 focusing horns to select neutrino beam with a decay pipe 194m long x 4m diameter, He filled

Comparison with T2K

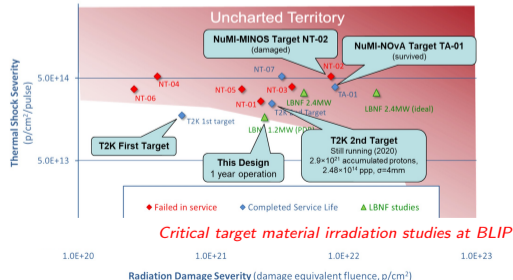

- Higher beam power but lower current and smaller beam spot = lower proton fluence and thermal shock than T2K
- Longer target will require optimised design of cantilever support

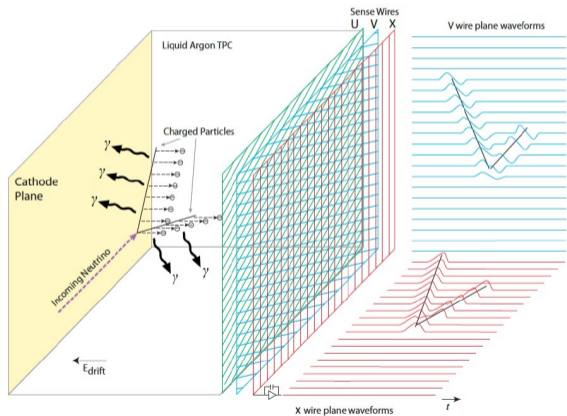

To scale. Core length = 0.9m T2K, 1.5m LBNF

Parameter	LBNF Design (1 Year Design Life)	T2K Experience (Target 2 History)
Beam Power (MW)	1.2	0.51
Proton Energy (GeV)	120	30
Beam Current (μA)	10	17
Beam Sigma (mm)	2.7	4
Radiation Damage Severity (p/cm^2)	$2.5\text{E}+21$	$3.1\text{E}+21$
Thermal Shock Severity ($\text{p}/\text{cm}^2/\text{pulse}$)	$1.7\text{E}+14$	$2.6\text{E}+14$

Graphite Neutrino Targets Exploratory Map

Single Phase “horizontal drift” LArTPC with 3 anode wire planes

DUNE “horizontal drift” TPC design by Bo Yu (BNL)

The DUNE anode wireplane assembly

The DUNE Phase I LArTPCs

- Both FD1 and FD2 are LArTPCs using highly modularized TPC design comprising $\mathcal{O}(100)$ identical TPC modules
- FD1 is a “horizontal drift” detector using 3 layers of wire planes vertical and $\pm 36^\circ$ - goes in the NE cavern
- FD2 is a “vertical drift” detector that uses 3 layers of strips on PCBs as the charge plane readout.

DUNE Physics Highlights

Summary

DUNE Near Detector (Phase I)

- Two components of the DUNE near detector:
 - ND-LAr + TMS (moveable)
 - SAND (stationary)

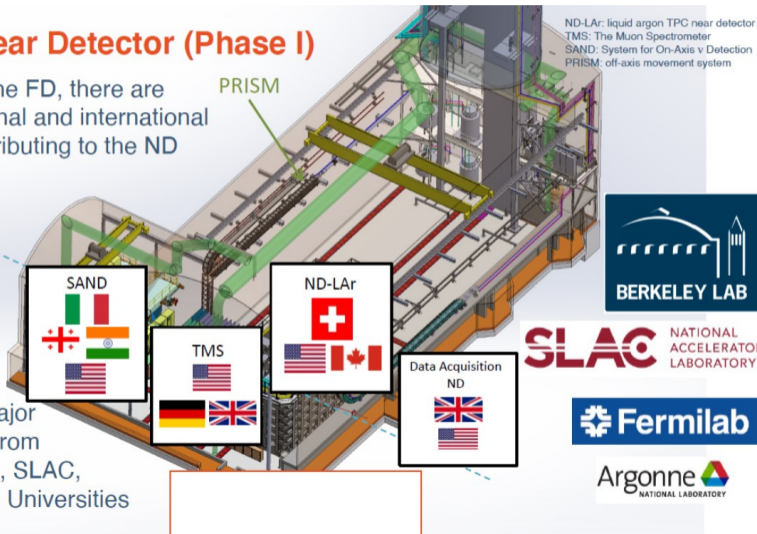

DUNE Near Detector (Phase I)

- Just as with the FD, there are multiple national and international partners contributing to the ND

- Our partners have been building prototypes & sending detector components

- In the U.S., major contributions from LBNL (pixels!), SLAC, ANL, FNAL, & Universities

DUNE Near Detector Status (Phase I)

- We are also building prototypes of the near detector
 - 2x2 Demonstrator in NuMI beam at Fermilab
 - Full Scale Demonstrator (FSD) of ND-LAR
- Important to test pixelated, modular design
- Like with the protoDUNEs, we will be getting physics out of ND prototypes
- ND-LAR **2x2 Demonstrator** is being installed in the NuMI beam
 - this will be the first ν data from DUNE*
- Also, KLOE magnet is currently being disassembled in Frascati for shipment to Fermilab for **SAND** National Institute for Nuclear Physics

Highlights

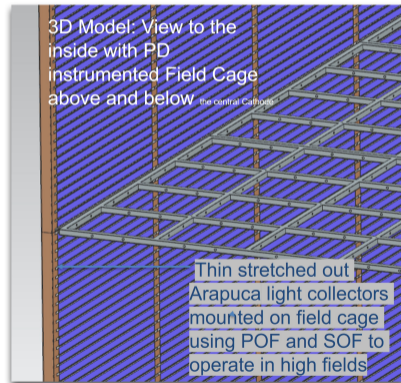

Summary

DUNE Phase II R&D

APEX system: light collectors deployed on field cage: FD3/4

Using FD2 technological breakthroughs like power-over-fiber and signal-over fiber to increase light collection by instrumenting the field cage.

50% of energy deposited in LAr is in light = improved calorimetry and energy resolution

Hybrid signals allow broad extension of DUNE physics

- CP violation with comparable sensitivity to 1 DUNE module
 - Low-Z target allows cross check with Hyper-K
 - Requires changes to ND suite
- Precision low-energy solar neutrinos (CNO, pep, ^8B MSW transition)
- Diffuse supernova background neutrinos
- Literally complementary supernova burst signal: anti- ν_e vs. ν_e
- Eventual $0\nu\beta\beta$ experiment with sensitivity beyond inverted ordering

Broad international community interest, with opportunity for new funding sources

Novel target medium: (Wb)LS

Novel light sensors: LAPPDs, dichroicons

New technologies make this possible

DUNE Phase II ND Workshop, ICL, JUNE 2023

ND-GAR AND ITS REQUIREMENTS:

ND-M2 Measure outgoing particles in ν -Ar interactions with uniform acceptance thresholds than a LArTPC, and with minimal secondary interaction

- ND-C3.2 ND-GAR shall detect protons with KE >10 (5 MeV goal)
- ND-C3.3 ND-GAR shall detect charged pions with KE >20 (5 MeV goal)
- ND-C3.4 ND-GAR shall reconstruct charged tracks with a momentum resolution better than tbd
- ND-C3.5 ND-GAR shall identify charged particle types with better than tbd
- ND-C3.6 ND-GAR shall identify and reconstruct photons with energy resolution better than tbd and energy resolution better than T
- ND-C3.7 ND-GAR's calorimeter shall measure the timing for at least one neutrino interactions with TBD timing resolution

Requirements were motivated by:

- 0.5 Tesla superconducting solenoid with "partial yolk"
- 10 B high precision TPC (LiD+TPC)
- Studies showing the inability to fully characterize

Takeaways

o DUNE-ND (especially with Phase II) will redefine our understanding of dark sector searches. Let's take advantage of it!

Upgrade ideas for ND-LAR

Aim is to suggest additional potential modifications to ND-LAR that might enhance its capabilities

- Upgrades without touching the inner detector hardware or emptying LAR
 - Xenon doping
 - Upgrade of the Off-detector electronics
 - Adding a Rock muon tracker in front of ND-LAR
 - Better Calibration with 220-Rn injection
- Some hardware modifications (empty LAR)
 - Improve neutron detection methods by upgrading optical detectors (Li-Glass)
 - Replace charge tiles of a module with smaller pixels and lower thresholds
 - Photosensitive dopants
 - Use Radio-Pure Underground Ar
- Significant Modifications
 - Magnetize ND-LAR
 - All detector upgrades
 - Magnetize ND-LAR

Summary

DUNE Phase I - determines the mass ordering

Data points show NO,
 $\delta_{CP} = 0, \sin^2\theta_{23} = 0.5$

Neutrino mode

Phase I

Antineutrino mode

Rich spectral information = unmatched sensitivity to osc. parameters

DUNE Phase II - measures δ_{CP} , θ_{23} octant

Data points show NO,
 $\delta_{CP} = 0$, $\sin^2\theta_{23} = 0.5$

Neutrino mode

Phase II

Antineutrino mode

Rich spectral information = unmatched sensitivity to osc. parameters

CP Violation Sensitivity

Mass Ordering Sensitivity

DUNE will determine MH unambiguously and CPV to 5σ (50% of δ_{CP})

Sterile ν Searches

Inelastic Dark Matter Scattering

- DUNE has unique sensitivity to the ν_e flux
- Studies using ν_e electron scattering indicate 5% pointing resolution

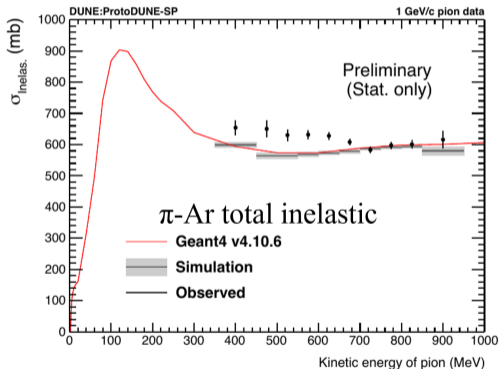

- **Phase I:** $\mathcal{O}(100)$ s events per FD module for galactic SNB
- **Phase II:** Reach extends beyond Milky Way. Enhancements to LArTPC design in Phase II could significantly improve low-energy physics.

Summary

Neutrino long-baseline oscillations offer a unique opportunity to search for CP violation, unravel the mass ordering of neutrinos, and search for physics beyond the Standard Model.

- **LBNF/DUNE are “best-in-class” facilities/experiment for precision measurements of neutrino oscillations with unique sensitivity to Supernova burst astrophysics and beyond the Standard Model searches in both near and far detectors**
- **The LBNF far site excavation is near completion (expected early 2024), the DUNE far detector cryostats are under fabrication (CERN contract) and the detector components for FD1 and 2 are under construction.** Near detectors are in final prototyping phase.
- **DUNE collaboration now comprises ~ 1400 active collaborators and 37 countries.**
- **DUNE experiment is highly internationalized with non-US contributions to the detectors exceeding 50%. The first large scale multi-lateral MOU between DOE and multiple international partners was signed on Nov 17,2023**
- **DUNE physics output continues to grow with real data analysis from prototypes as well as advances in simulation and reconstruction and pursuing new physics ideas.**
- **DUNE Phase II R&D effort is growing with large international and US effort already underway. US Phase II plans were presented to P5 - expecting report Dec 6-7,2023.**
