# The HEXPLIT algorithm in ElCrecon

Dr. Sebouh J. Paul 12/12/2023

#### Intro

- HEXPLIT\* was developed to improve the position reconstruction in sampling calorimeters by taking advantage of staggered layouts
  - Improves spatial resolution by a factor of ~2
- The HCal Insert and the SiPM-on-tile ZDC are examples of detectors that can take advantage of this algorithm
- The algorithm was originally written as a stand-alone program in Python
- Now a C++ implementation has been added to the EICrecon on a branch\*\*

\*arXiv:2308.06939

\*\* https://github.com/eic/EICrecon/blob/sipmzdc/src/algorithms/calorimetry/HEXPLIT.cc

### Two components to HEXPLIT (separate algorithms)

- Subcell reweighting
  - Creating subcell hits with energies determined by those of the overlapping hits in neighboring layers,
- Position determination
  - Determine the position of the center of the shower by weighting each (subcell) hit by the log of its energy, with a cutoff determined by the total shower energy
- These algorithms are respectively called HEXPLIT and LogWeightReco in the ElCrecon
  - LogWeightReco can run independent of whether the input hits are normal hits or subcell hits
- These algorithms and their factories have been added in ElCrecon

#### **HEXPLIT** algorithm

Formula for subcell reweighting

 $W_{i} = \prod_{j=1}^{N-1} \max(E_{j}, \delta), \quad \text{Product over overlapping cells, } j, \text{ in neighboring layers}$  $E_{i} = E_{\text{tile}} W_{i} / \sum_{j} W_{j}. \quad \text{Energy in a given subcell, } i$ 

 $\delta$  = energy threshold, set to 1 MIP.

#### LogWeightReco algorithm

Reconstruct shower from (subcell) hits

Core

 $\vec{x}_i w_i$  $\vec{x}_{recon} = \frac{\vec{i} \in \text{subcells}}{\sum}$ i∈subcell

$$w_i = \max\left(0, w_0 + \ln\frac{E_i}{E_{\text{tot}}}\right)$$

 $w_0$  is cutoff parameter, fine-tuned as a function of the reconstructed particle energy

$$w_0 = \texttt{w0\_a} + \texttt{w0\_b}\log rac{E_{ ext{recon}}}{\texttt{E0}} + \texttt{w0\_c} igg(\log rac{E_{ ext{recon}}}{\texttt{E0}}igg)^2$$

$$E_{ ext{recon}} = \sum_{i \in ext{hits}} E_i / ext{sf}$$

#### ZDC plugin (for SiPM-on-tile ZDC)

Added these algorithms' factories in the chain of factories in the ZDC SiPM-on-tile's reconstruction

#### Performance

Position obtained with C++ implementation is consistent with the results we got earlier with the Python implementation.

ZDCLogWeightClusters.position.x[0]-ZDCLogWeightClusters.position.z[0]\*MCParticles.momentum.x[2]/MCParticles.momentum.z[2]

#### Summary

- HEXPLIT has been incorporated into ElCrecon
- Shower-position reconstruction is now its own separate algorithm
- Both algorithms could be used in the context of either the SiPM-on-tile ZDC or the calorimeter insert.
- These have been included in the sipmzdc branch; to be pull-requested into the main branch soon.

H4 staggering

## Energy dependence of position resolution

• H4 staggering improves the resolution by up to 60%, when utilizing the HEXPLIT algorithm
