

# LFHCAL Test Beam August/September 2024

Oskar Hartbrich  
(for the LFHCAL testbeam crew)

ORNL is managed by UT-Battelle LLC for the US Department of Energy

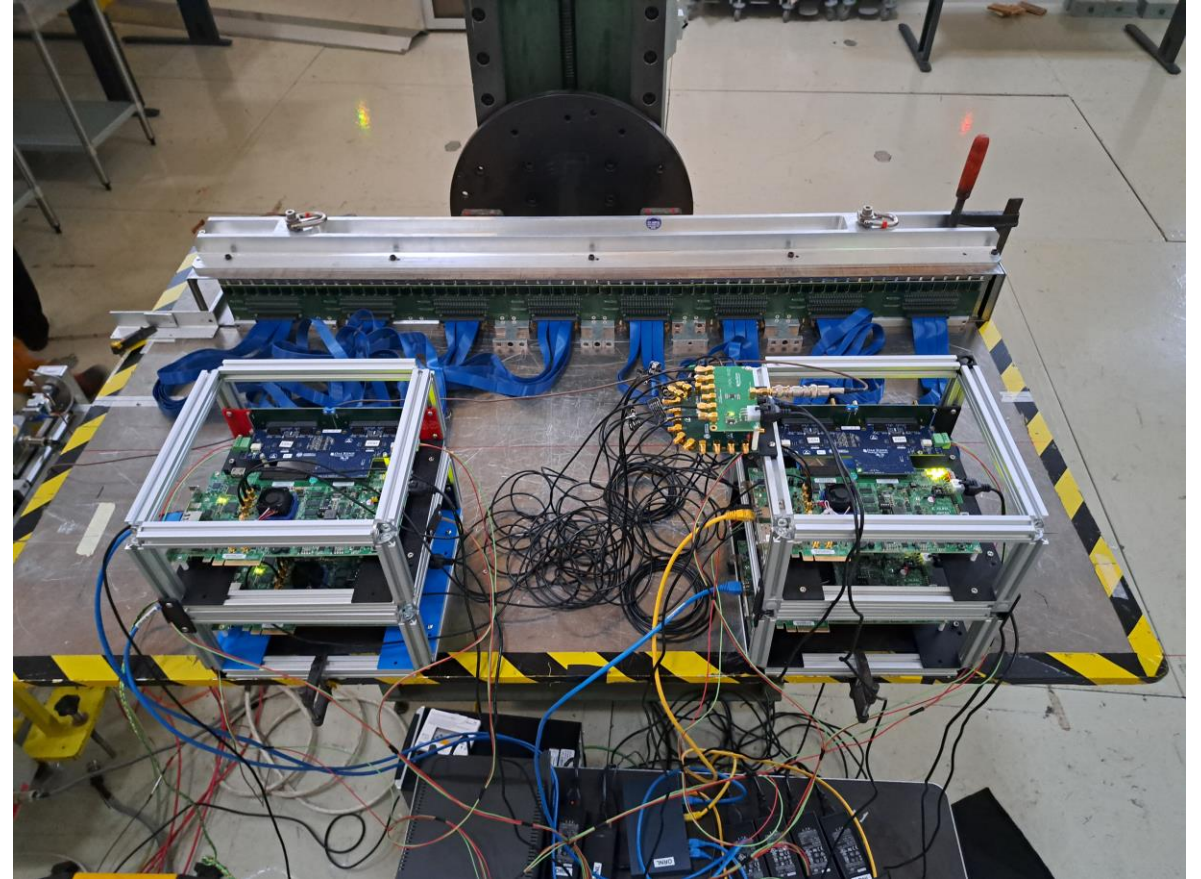

# LFHCAL Prototype: The Plan

- Two continuous weeks of beam time at CERN PS.
- **August 28-September 11**
- First week: HGCROC Readout
- Second week: CAEN DT5202+DT5215 Readout

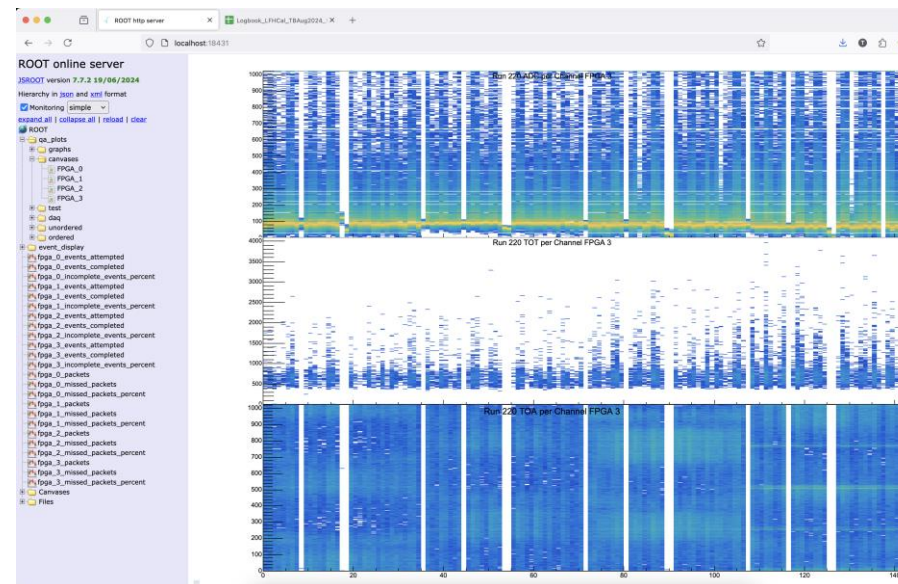

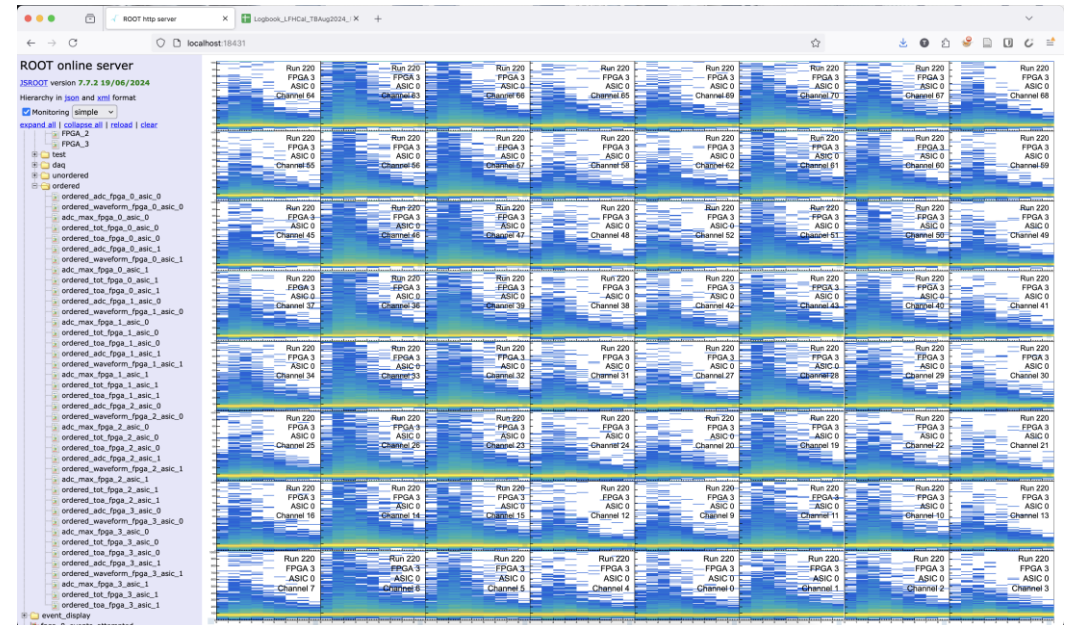

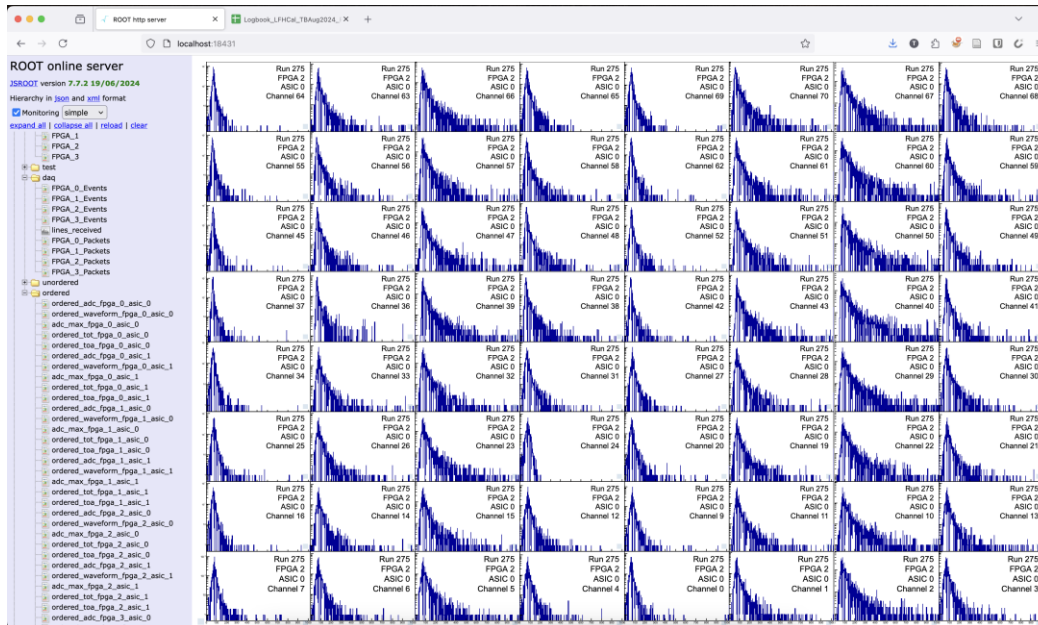

# HGCROC Run Summary

- Setup without major issues
- First useful runs within hours of setup, needed some calibrations
- Trigger rates very very low (single digit events per spill)
  - Ultimately traced down to misconfigured FOCAL trigger board
- Still acquired full dataset:
  - Muons, electrons 1 GeV-5 GeV, hadrons (+-) 3-15 GeV
- All (coarsely) QA'd by Tristan Protzmann's live data monitor

# HGCROC Run Summary

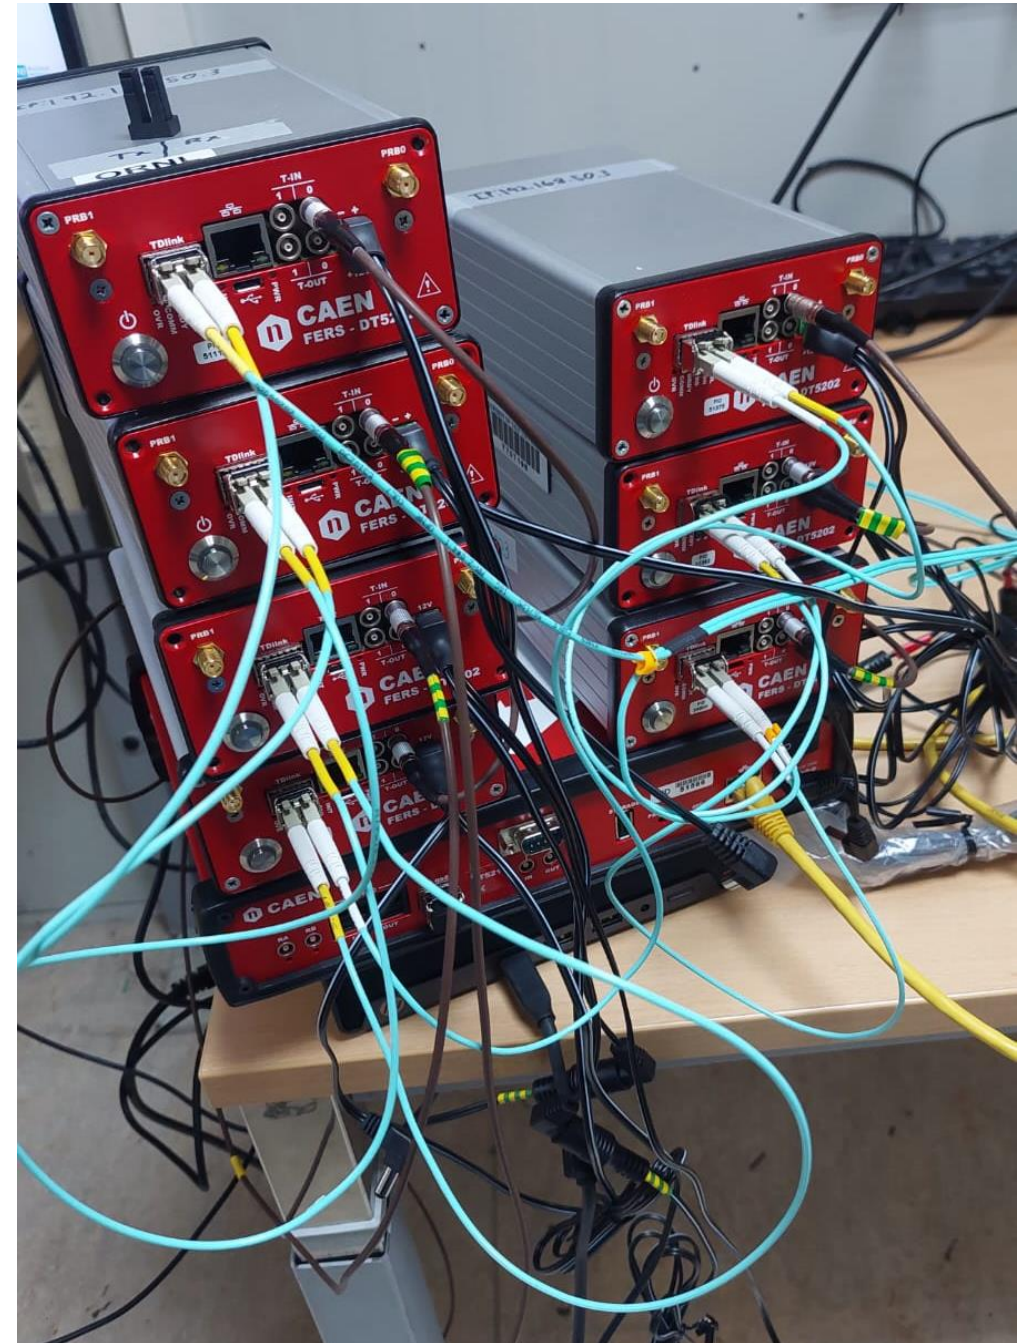

# HGCROC Run Summary

# The CAEN Saga pt1

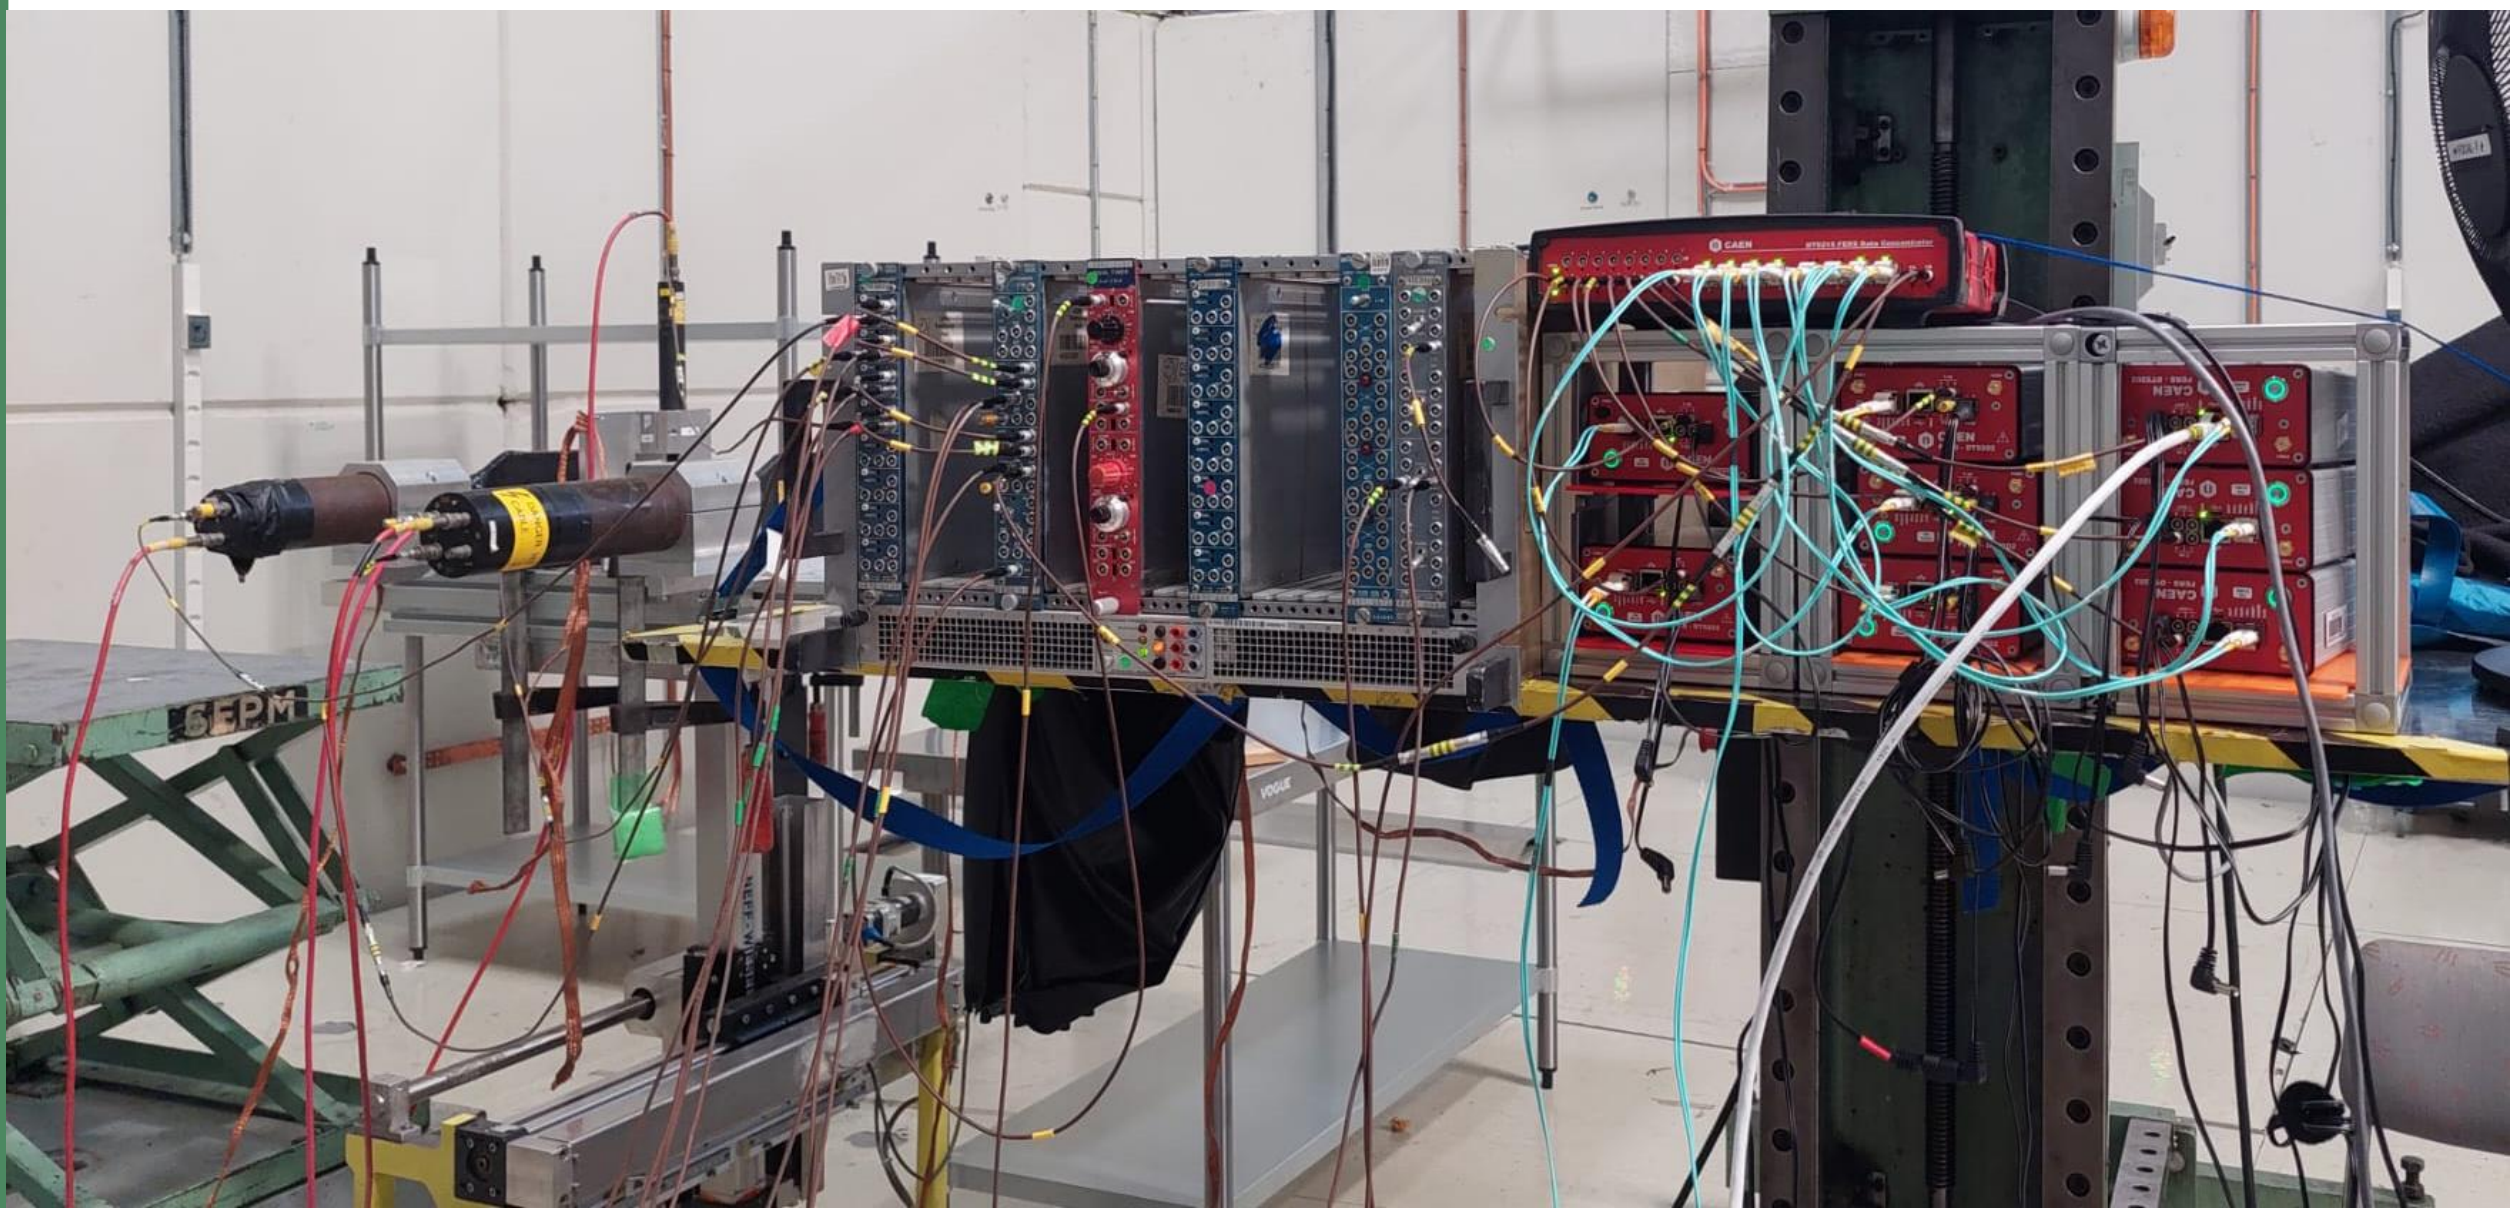

- 8 DT5202 readout units + 1 DT5215 data concentrator
  - Using several loaned DT5202s from all over the world
  - Readout PC <-> single ethernet <-> DT5215 <-> “TDLink” fibers to DT5202
- Cabled up everything: pedestals good
  - No grounding issues, no ground lift to flex boards necessary (PS testbeam is cleaner environment than bldg. 6000)
- However: no signal whatsoever.

# The CAEN Saga pt1

# The CAEN Saga pt2: Fighting for Nanoseconds

- Trigger signal propagation delay too long.
- Did everything to reduce latency.
  - Smallest number of devices in chain, shortest cables, optimized geometry.
  - DT5215 integrated trigger fanout has 20ns delay by itself (CAEN confirmed this...)
- Increased shaping time of DT5202 to maximum
  - 87.5ns up from 25ns
  - Will need conversion factor between 25ns lab LED+cosmics and 87.5ns beam data...

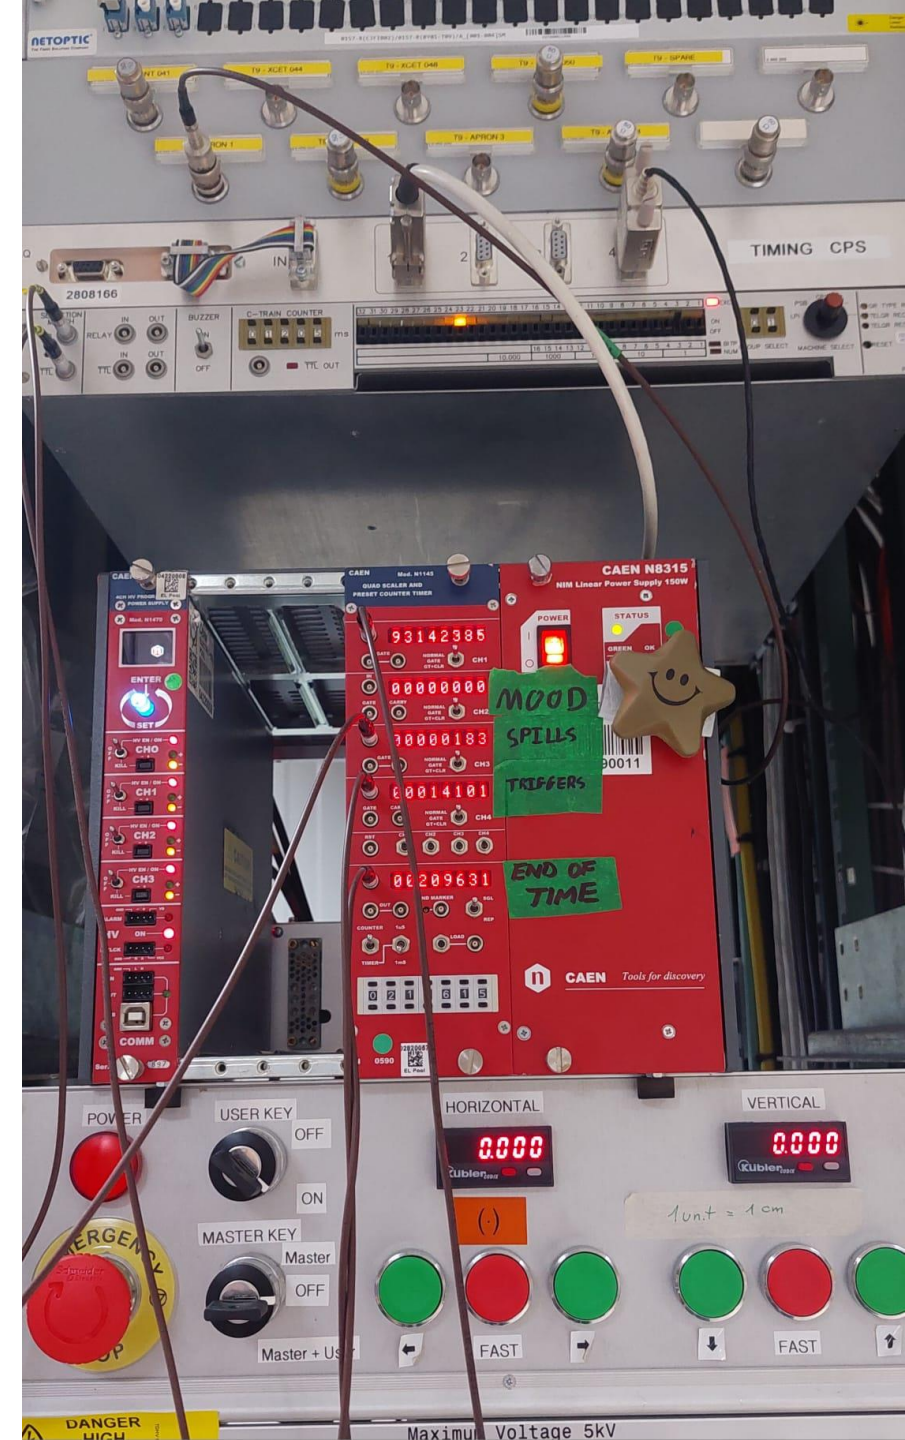

# The CAEN Saga pt3: Fighting TDLinks

- Found the signal, but readout super unstable
  - Crashing every 0-5 minutes
  - Most likely due to instabilities in “TDLink” between units
- Suspected temperature issues,
  - Stripped all CAEN units of their casing and forced air through everything
- Contacted CAEN, had Zoom meeting with their engineers  
Friday afternoon: no result
  - New firmwares available with CRC checks, but made things way worse
- The mood got considerably worse at this point.

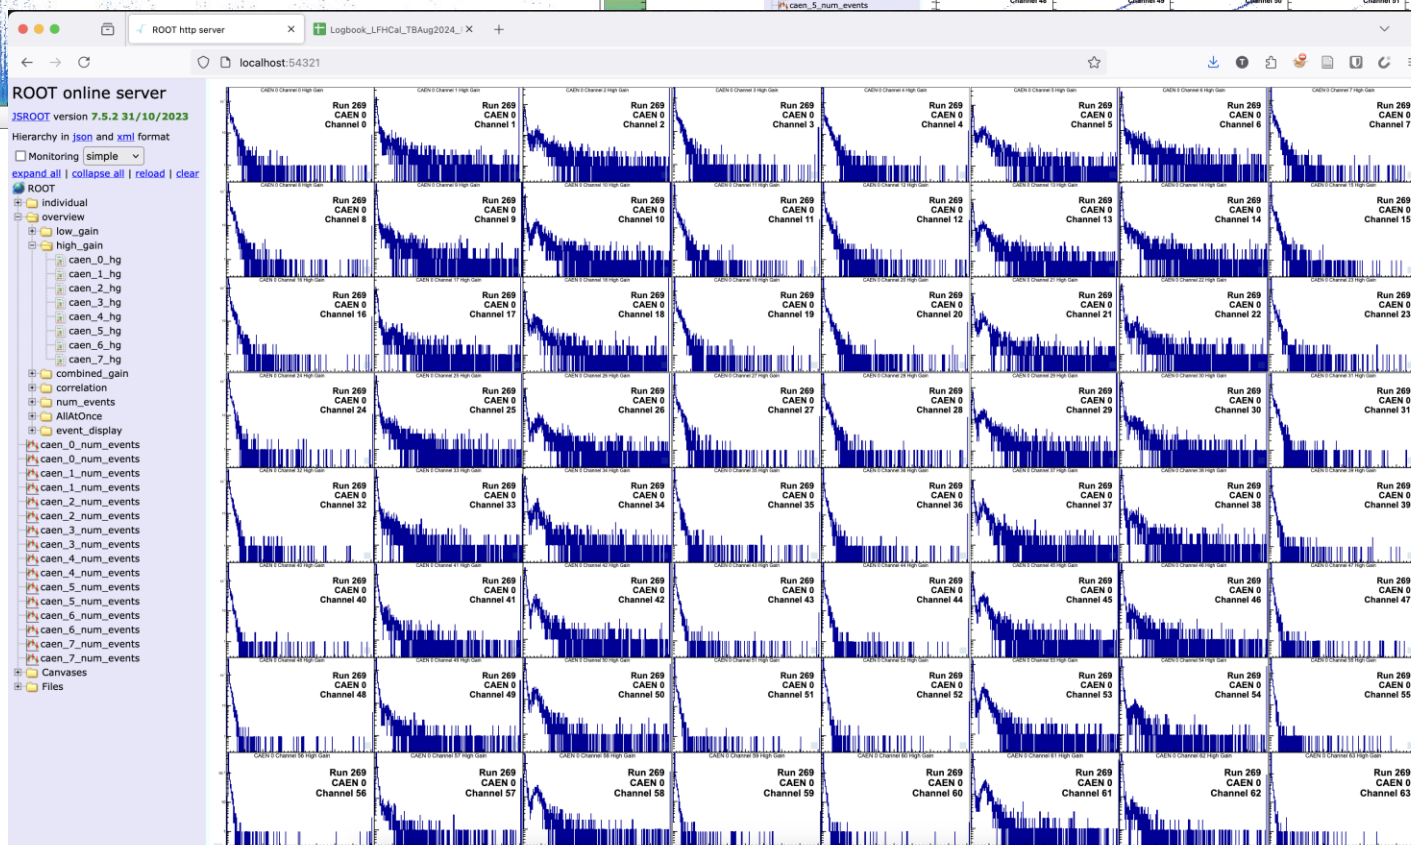

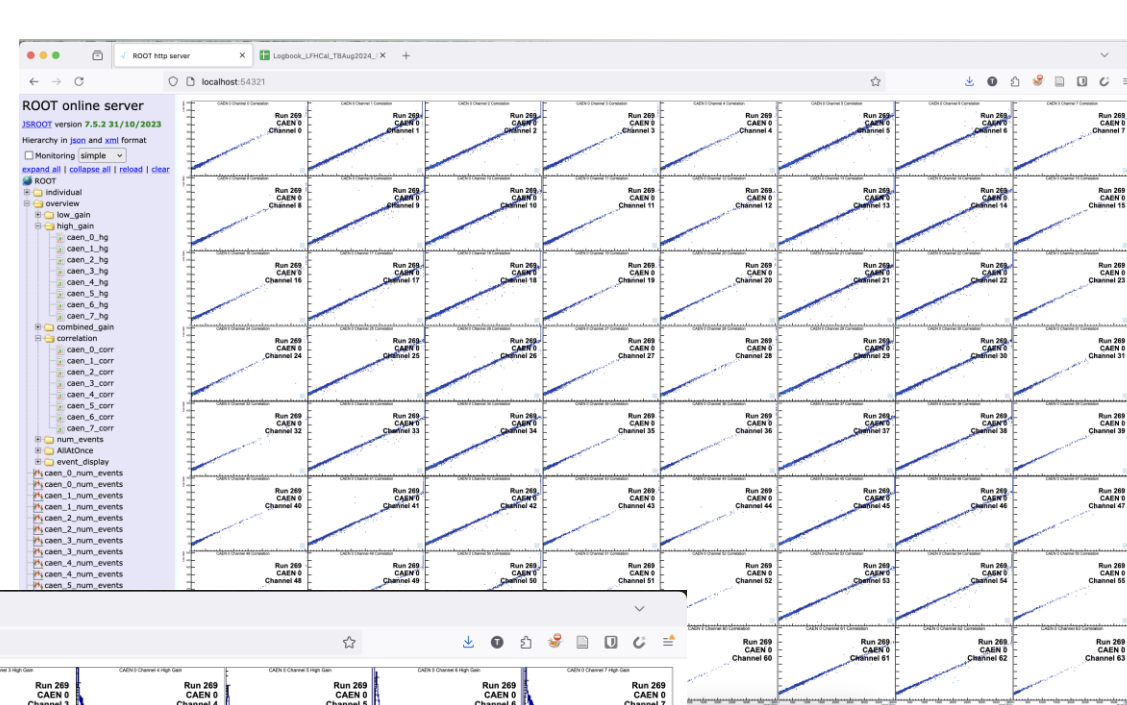

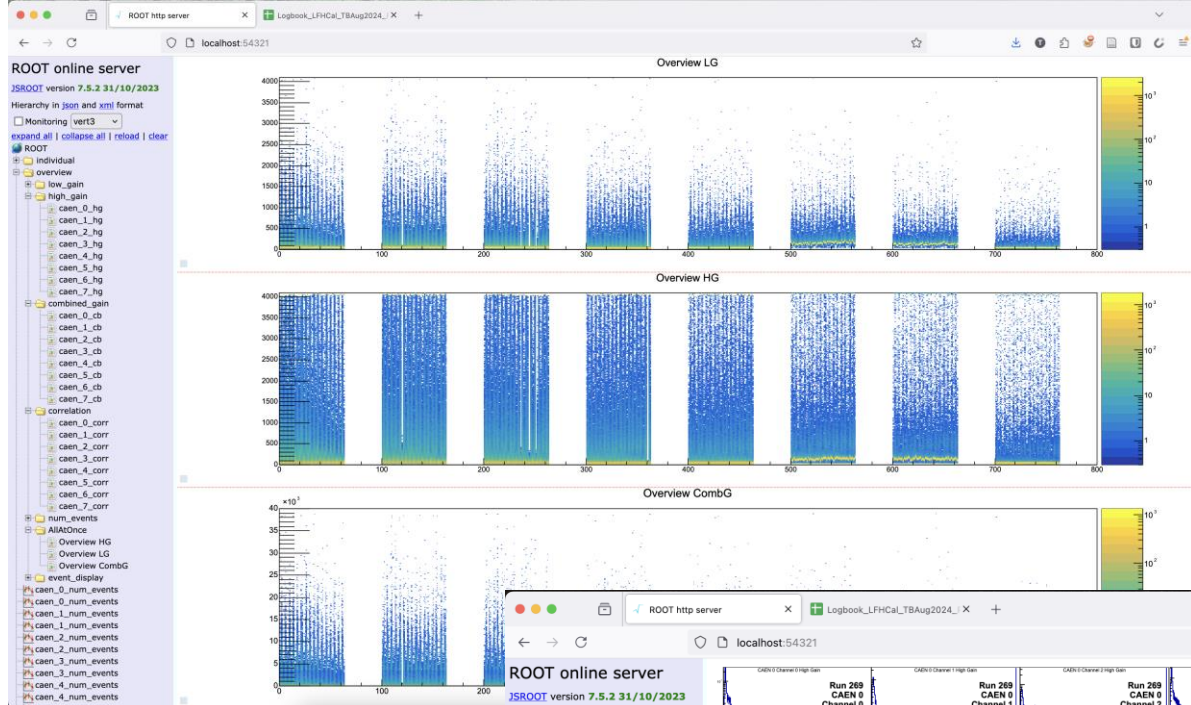

# pt4: Happily Ever After

- A terrible idea: why not get rid of the data concentrator?
  - DT5202 can be run individually in “parallel” via ethernet.
  - Asynchronous, but we distribute synchronous external triggers...
- Tried it out of sheer desperation. Works.
  - Needed some minor adjustments in trigger holdoff (maximum 600ish triggers per spill)
  - Shifter needs to make **really** sure all runs are started in between spills.
  - Otherwise no problems. Have not power-cycled a single unit in 4 days(\*).

# CAEN Run Summary

- Full muons, electrons, hadrons at 3 SiPM bias voltages
  - Full rerun of 45V bias point at the end for validation
- Muon scan with various shaper settings
  - To intercalibrate beam vs. lab measurements
- Full electron energy scan at 6 SiPM bias points total
  - Including dedicated muon calibrations before and after each electron scan
- All (coarsely) QA'd by Tristan Protzmann's live data monitor

# Shifters Summary

- Strong participation of various ePIC member institutes
  - Thanks to Fredi’s tireless advertisement and “encouragement” to join
- Special thanks for CERN-local support from FOCAL experts

# Analysis Plans

- Initial calibrations first:
  - Pedestals, MIP positions, HG/LG intercalibration (?)
  - Worked on by Thibor Bernardon (+ OH)
  - Have data for various configurations,
- Need a simulation model (!)
  - Some work has been done, but I'm unsure about the status
- Electromagnetic response (in MIPs) and resolution
  - Hit spectra vs. simulations: saturation effects in SiPM response?
  - Response/resolution vs. simulations
- IMO: Only then go towards hadrons after electrons are understood

# Summary

- Testbeams never work as planned.
  - Always stressful, but ultimately always quite fun
- Nevertheless very successful campaign
- All data backed up locally and on grid thanks courtesy of Bill.
- Testbeams are bad for your diet.
