

INTT cosmics analysis update

Wei-Che Tang, NCU

2024/10/23 group meeting

Cosmic analysis status

- Analyzed multiple runs. The information of the run is shown below:
 - Run number: 39524~39530
- Problem from last week:
 - In zr residual distribution, there is a peak around 0.04 cm.
 - > might be a sign of misalignment (?)

Fitting quality check

(Single run 39524)

- The reduced residual distribution in **xy plane**.
- Selected the tracks whose reduced residual is smaller than 0.02 as a good track.

Fitting quality check

(Combined run)

- The reduced residual distribution in **xy plane** for combined run.

Fitting quality check

(Single run 39524)

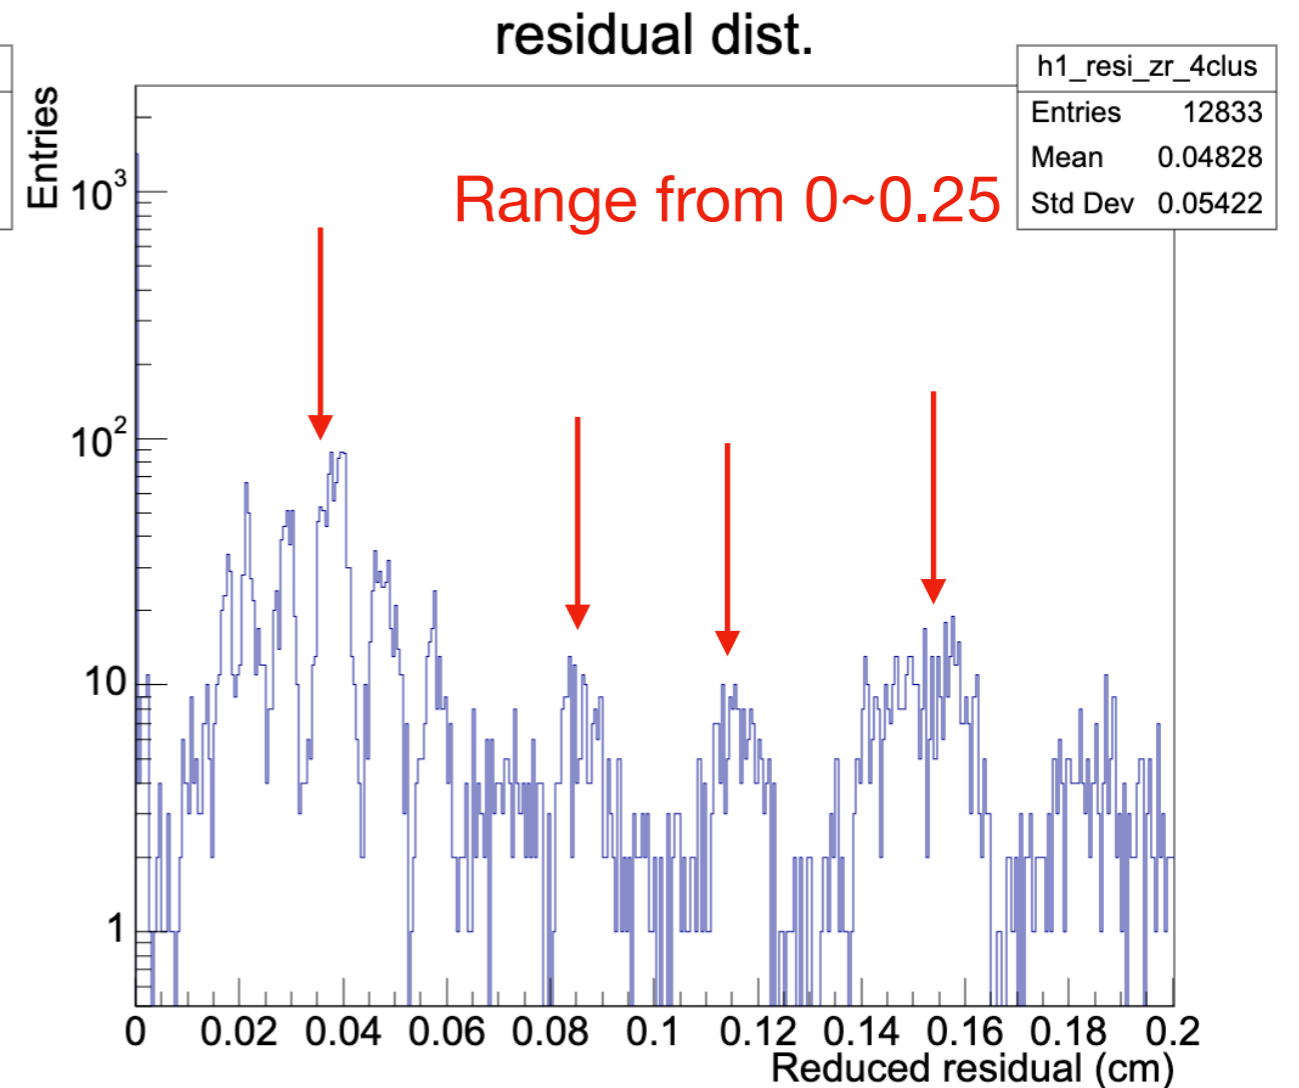

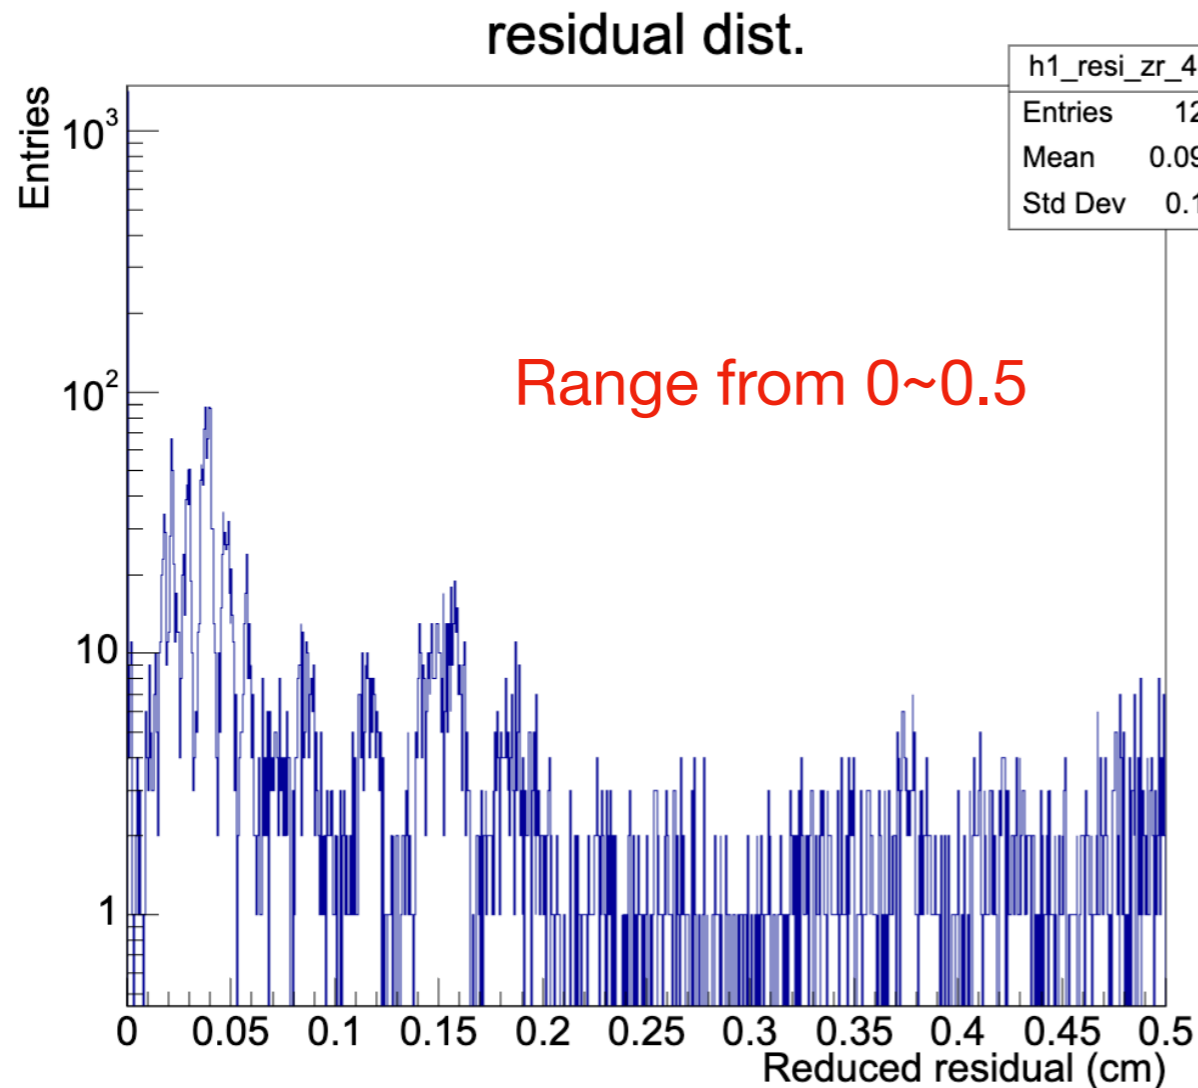

- The reduced residual distribution in **zr plane**.
- Selected the tracks whose reduced residual is smaller than 0.1 as a good track.
- There is a peak around 0.04.

Fitting quality check

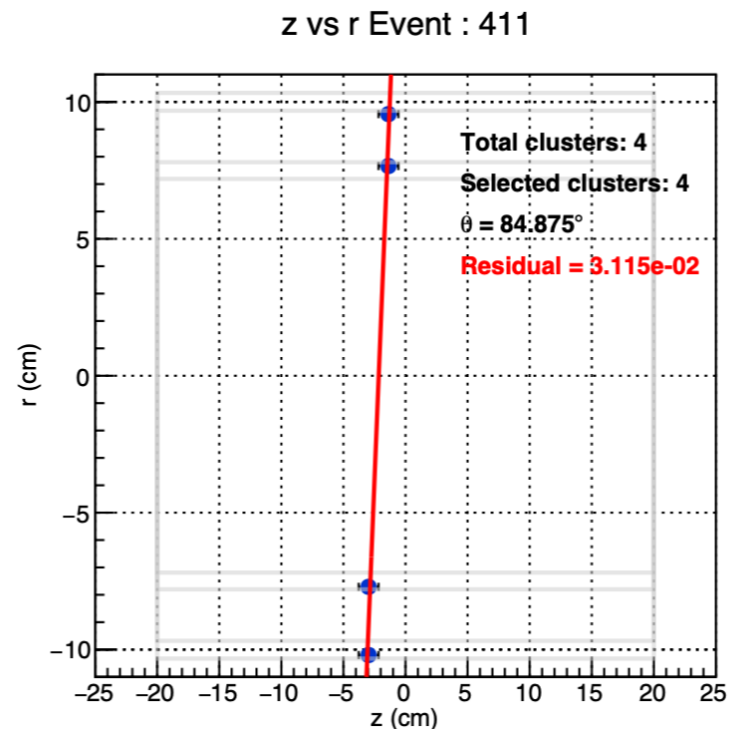

(Combined run)

- The reduced residual distribution in **zr plane**.
- More peaks appear in zr residual distribution in combined run.

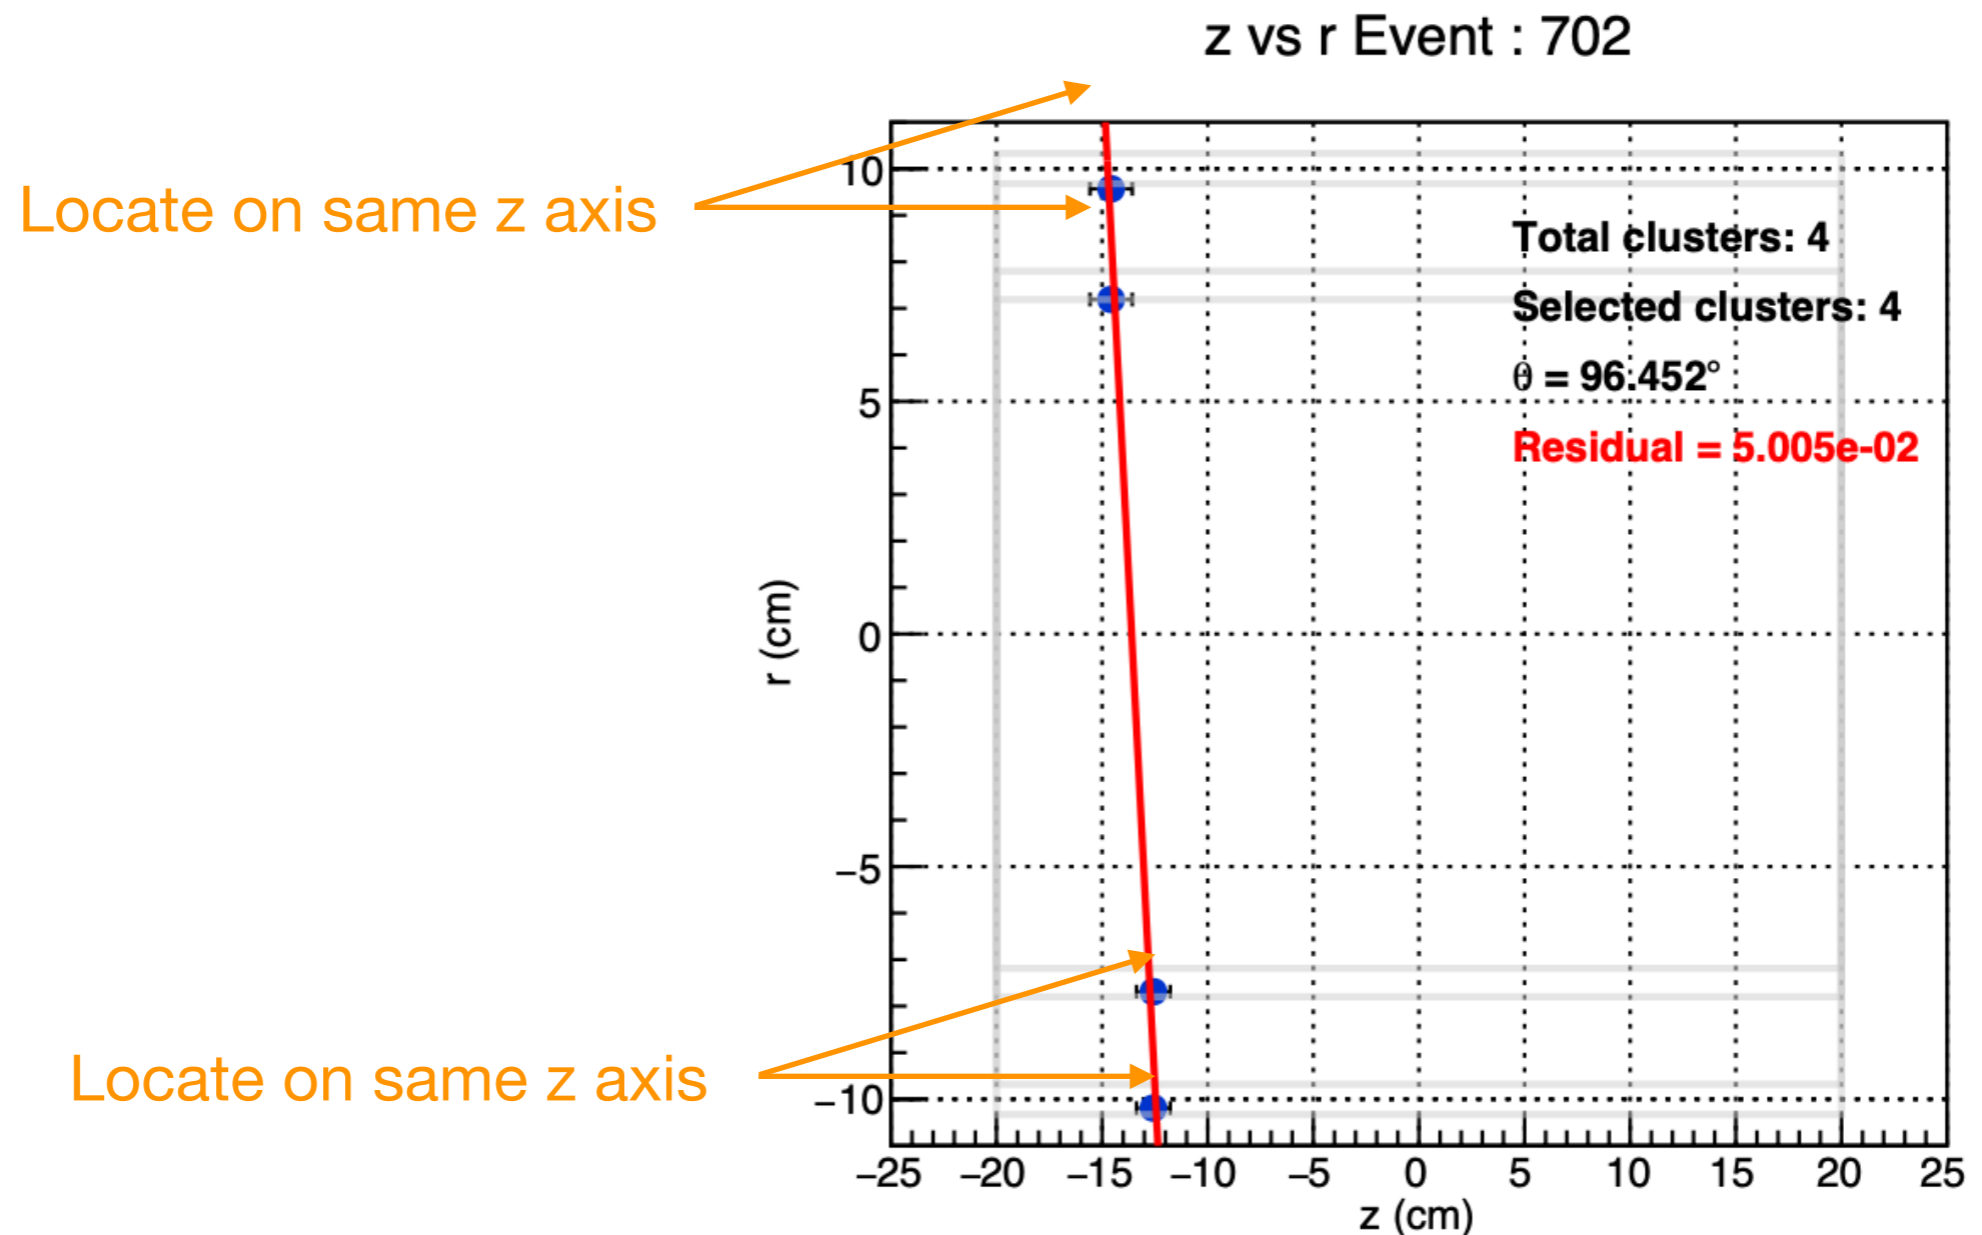

Event display check

- Take a look of event display where zr residual located at **0.02~0.06**.

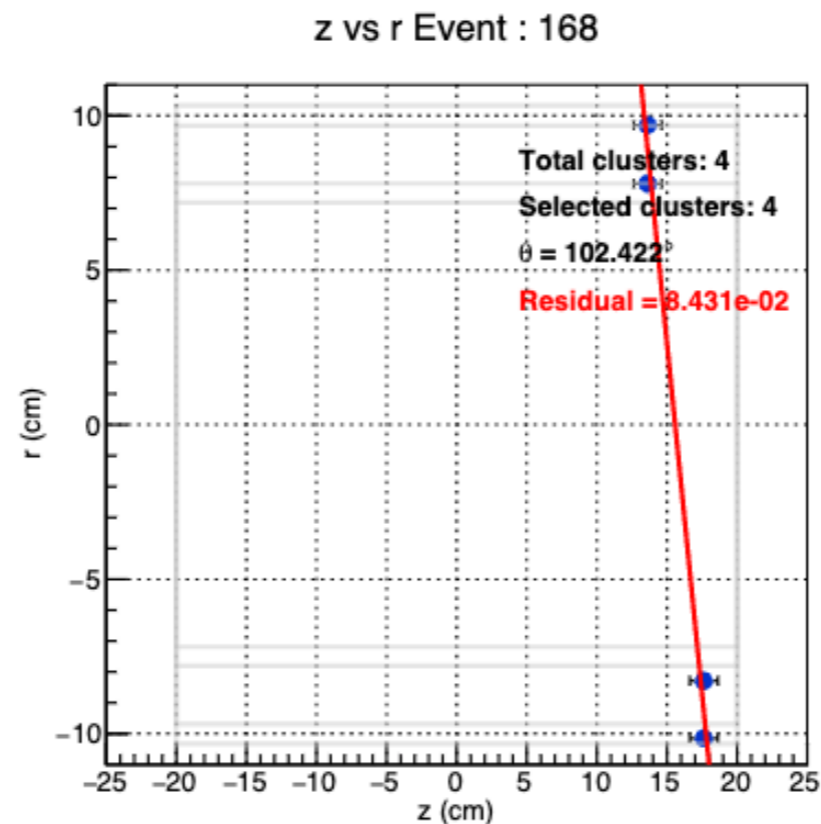

Run data check

- The event displays show that there is a pattern among those event.
- There is a z axis shift between upper hand clusters and lower hand clusters.
- The angle of these event is fix around 96° and 84° .

Event display check

- Another look of event display where zr residual located at 0.08~0.1.
- There is a z axis shift between upper hand clusters and lower hand clusters.
-> The shift is bit larger comparing to the previous event display.

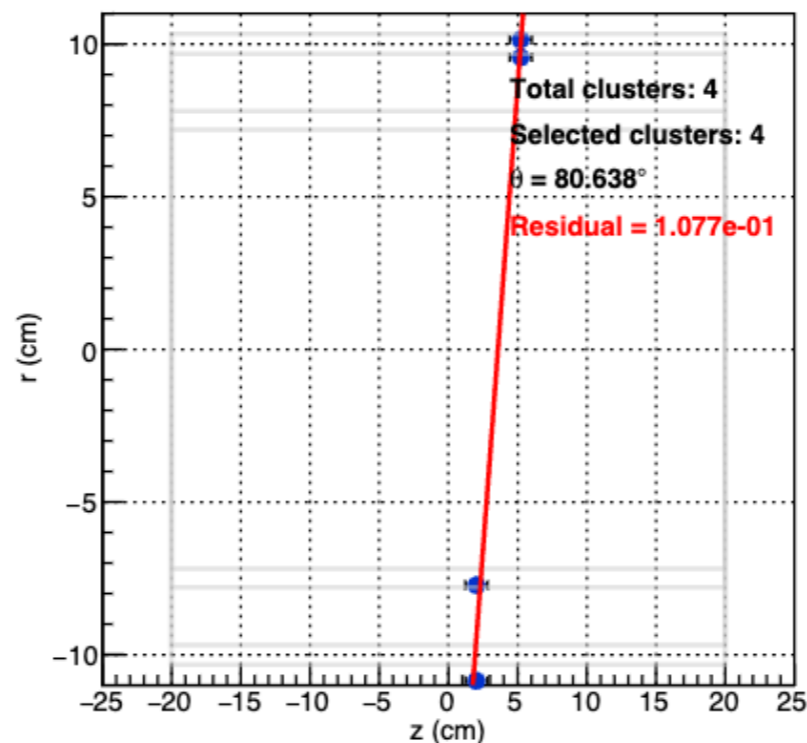

Event display check

- Another look of event display where zr residual located at 0.1~0.12.
 - There is a z axis shift between upper hand clusters and lower hand clusters.
- > Although there is larger residual in zr plane, all the clusters are still within the z acceptance.

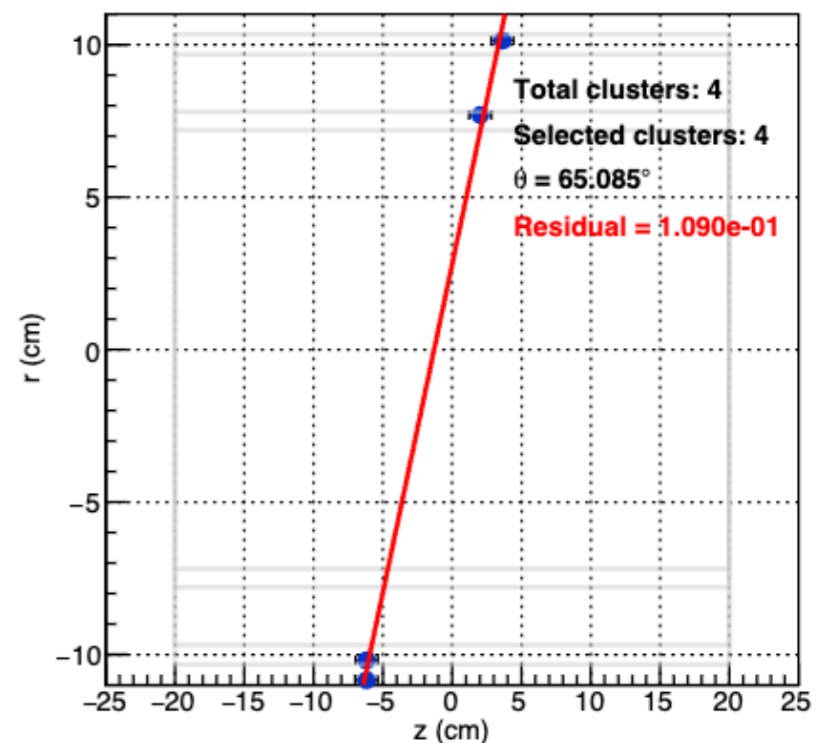

z vs r Event : 218

z vs r Event : 256

z vs r Event : 398

Conclusion

- Multiple runs are analyzed.
- Serval peaks found in zr residual distribution.
 - Take a look at the event display whose zr residual is located in those peaks.
 - No misalignment evidence is found, but a z position pattern of those events.
- We might have a too strict cut on zr residual.
 - No need to apply cut but check whether a fitting line is within the acceptance respect to the z axis.

Back up

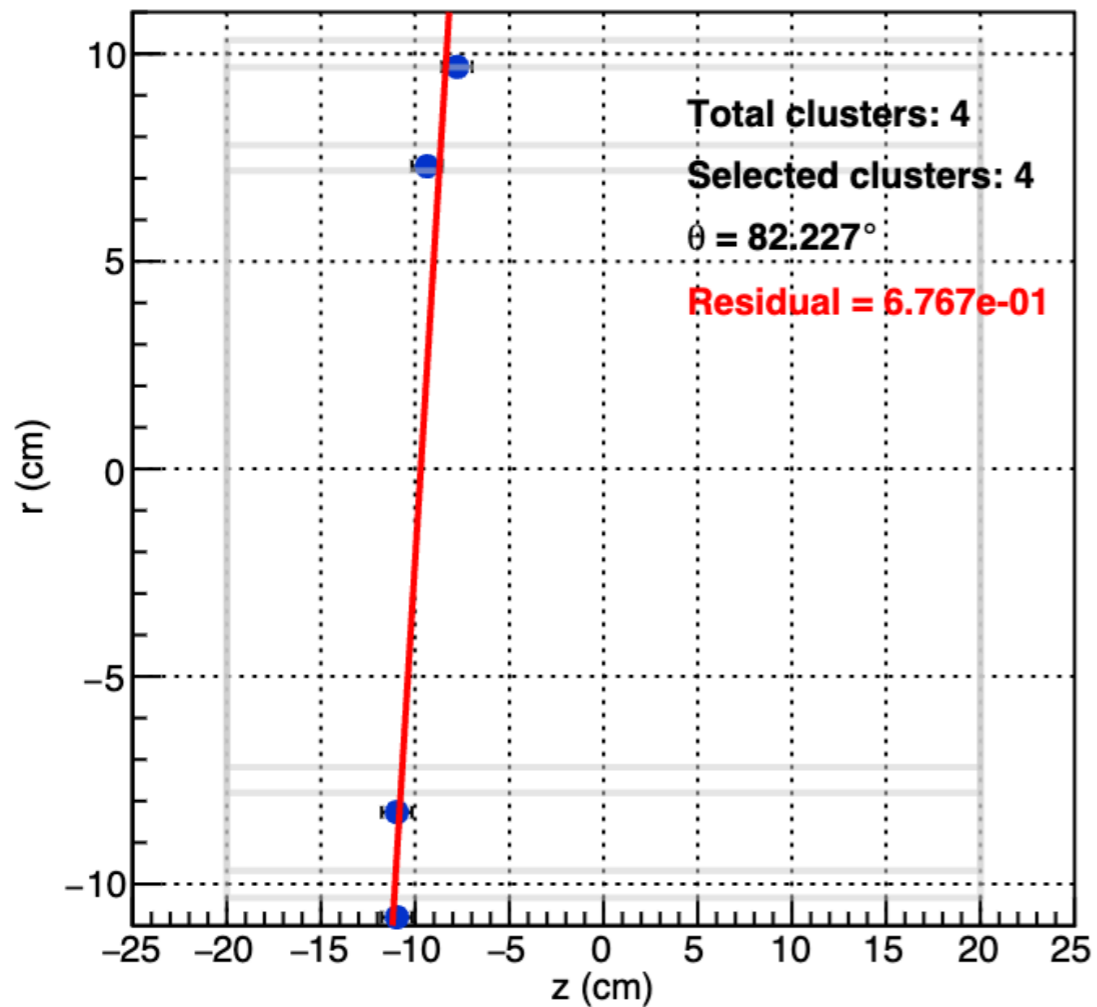

Cosmic analysis status

- Analyzed multiple runs. The information of the run is shown below:
 - Run number: 39524~39530
- Pre-selection for cosmic analysis:
 - Hot channel mask: (This applies before doing the clustering)
 - 13 hot channels are masked
 - Clusters cut:
 - Good cluster requirement: cluster adc > 15 & cluster size < 9 (adc0 is set to 15)

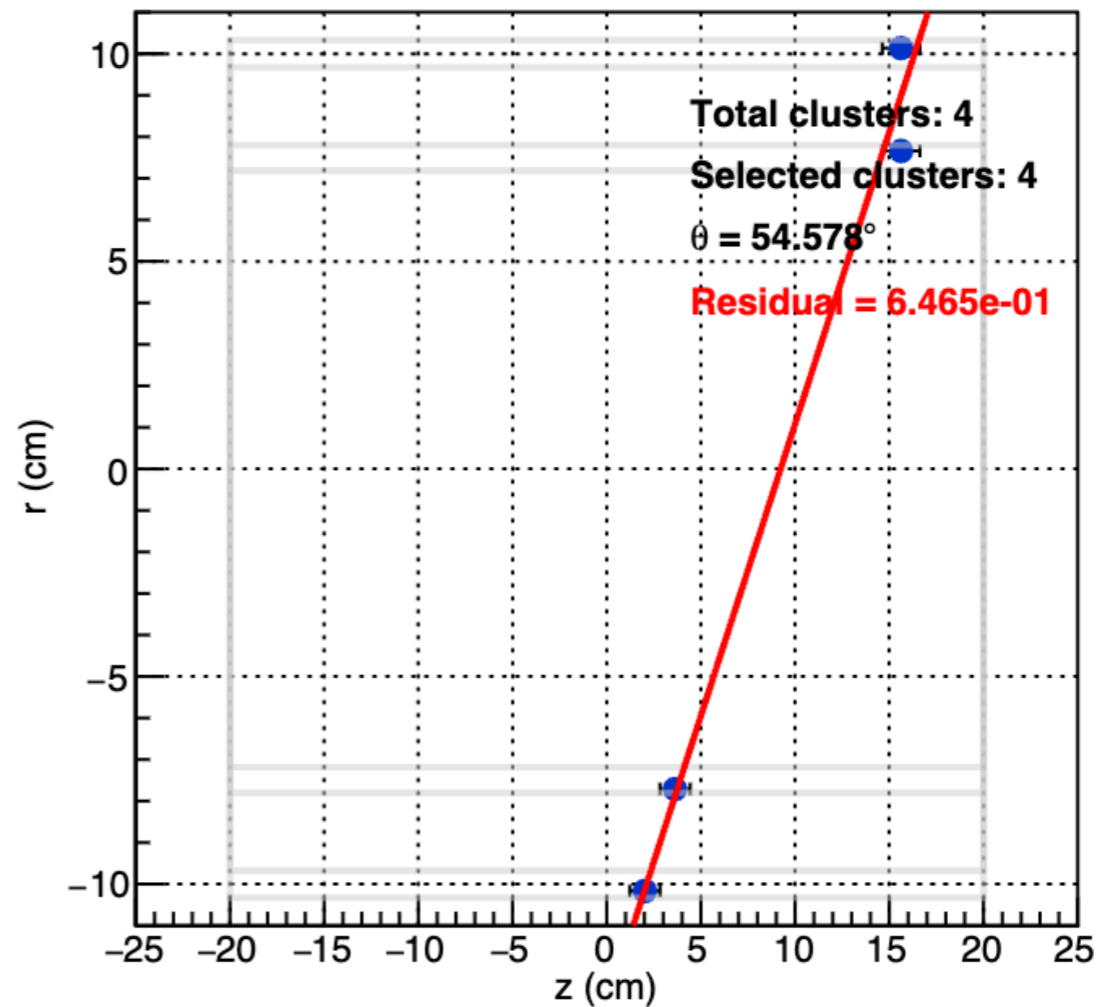

Event display check

- Another look of event display where zr residual located at 0.5~1.

z vs r Event : 20

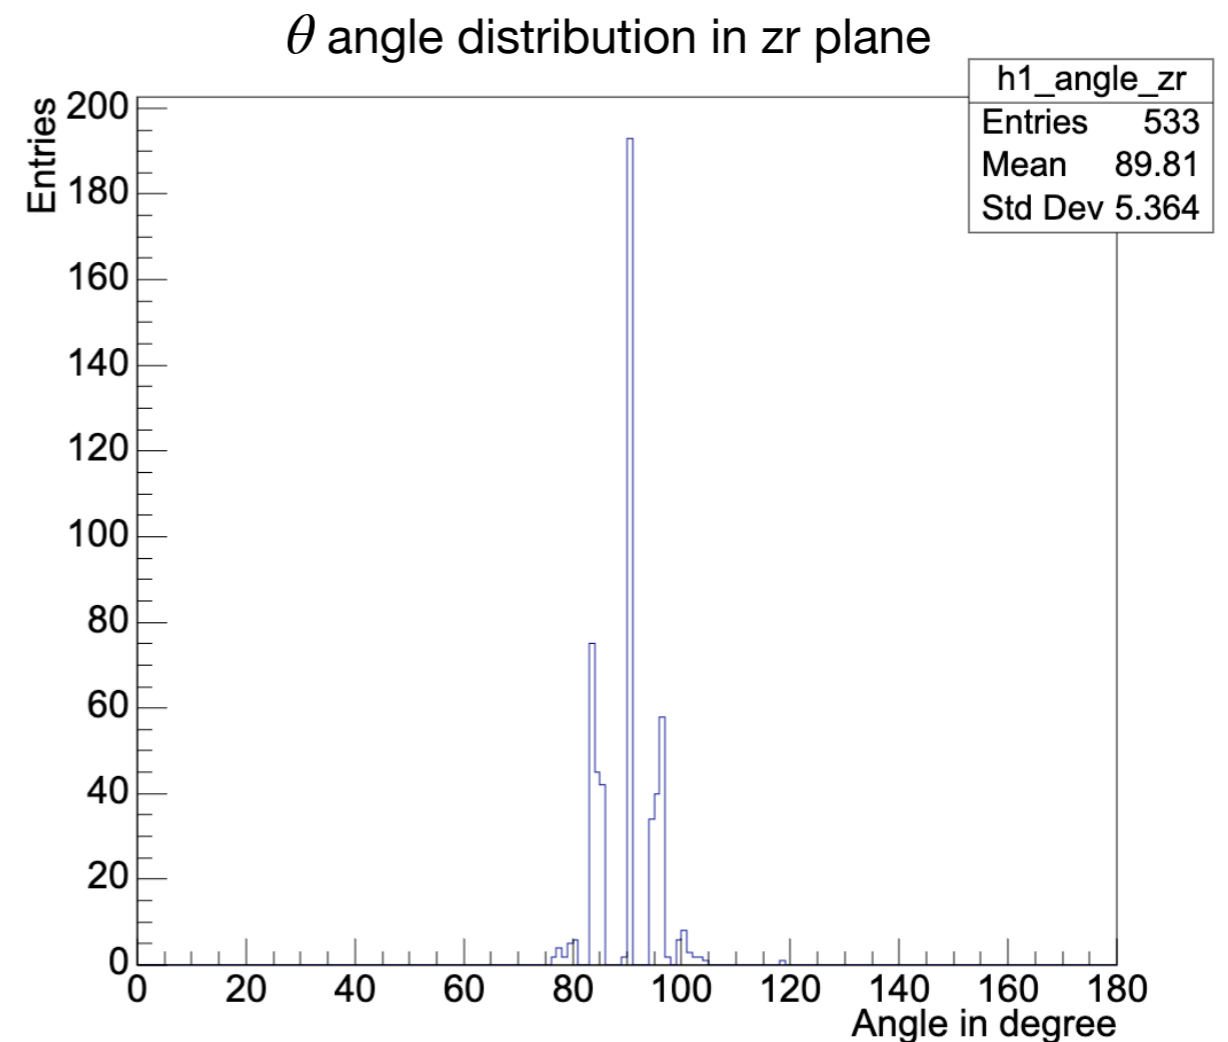

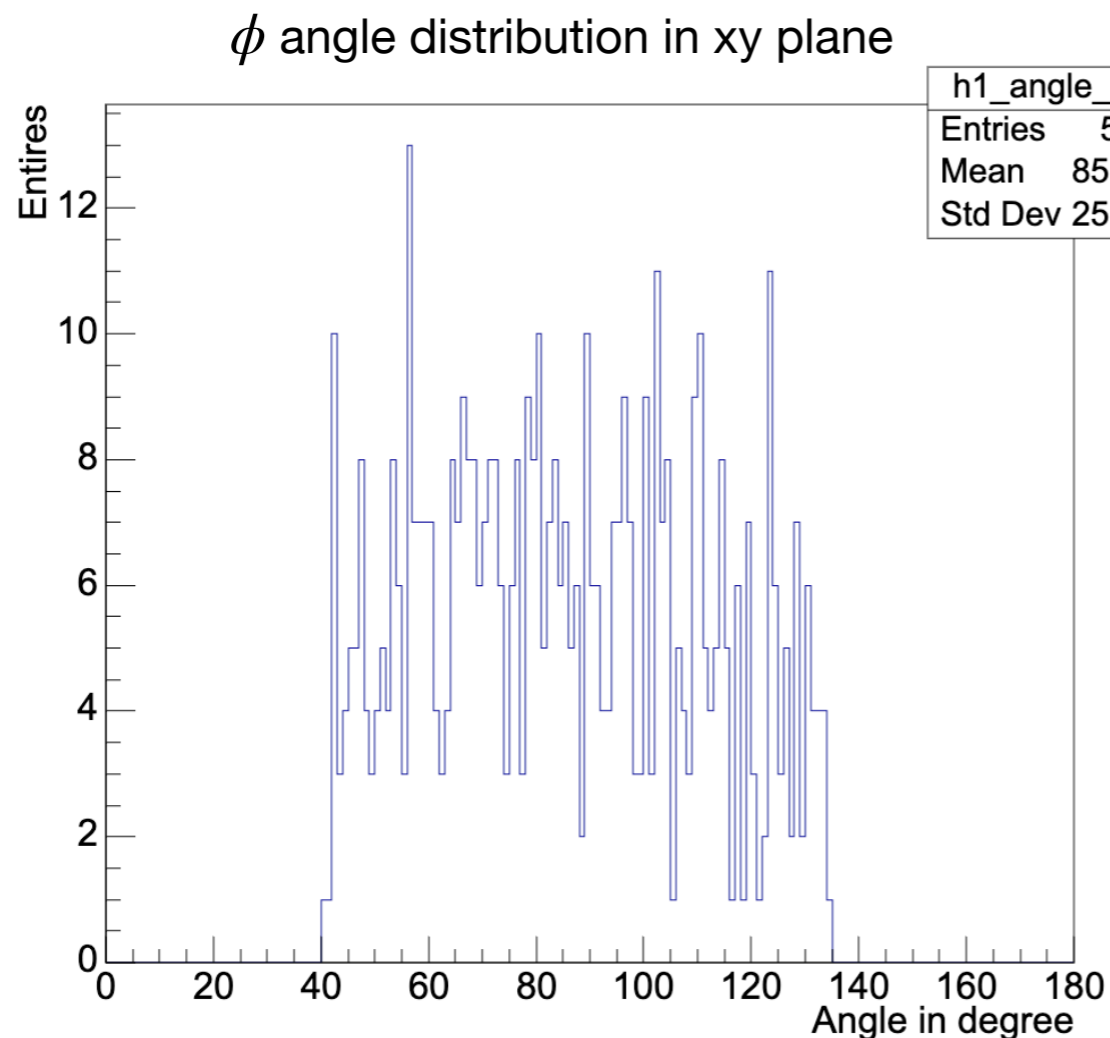

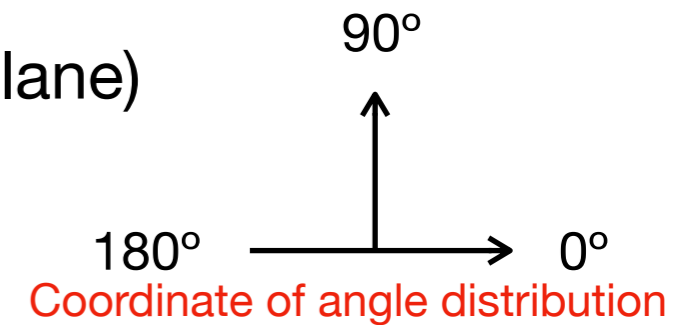

z vs r Event : 570

Angle distribution

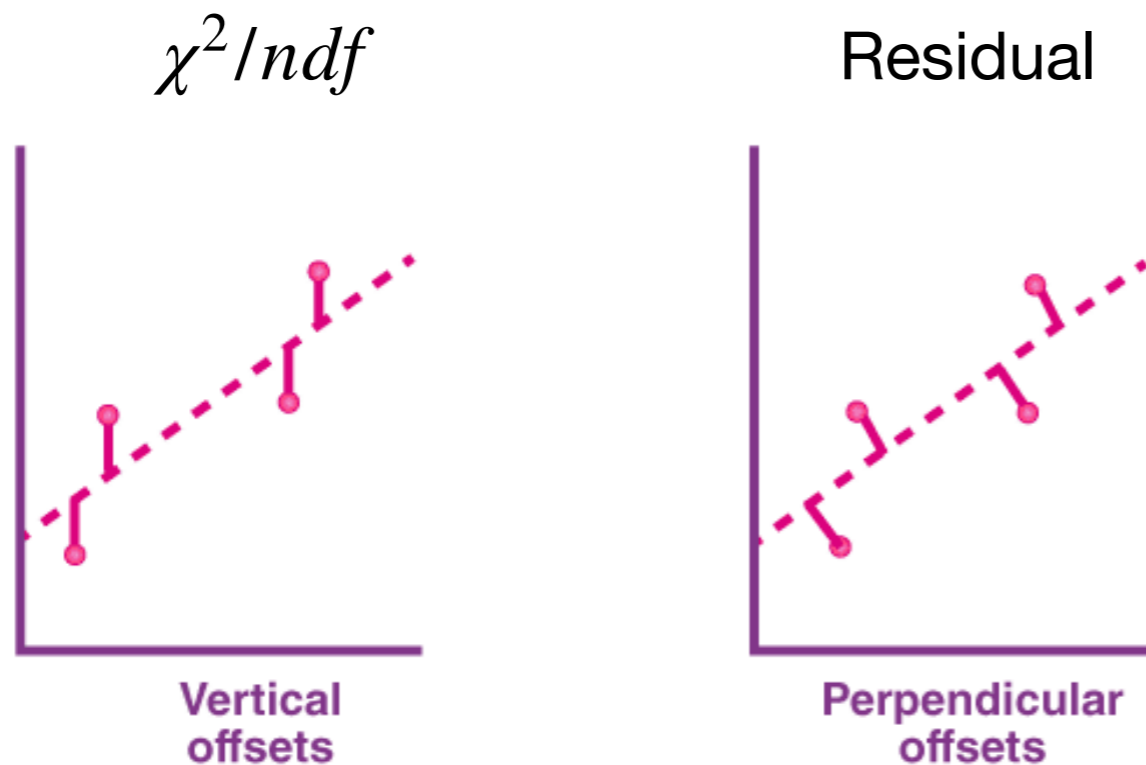

(Single run 39524)

- The distribution of the ϕ angle (xy plane) and θ angle (zr plane)
- Residual cut at xy residual < 0.02 and zr residual < 0.1 .
- The zr residual cut might be too tight for cosmic rays.

Residual distribution check

- The cosmic tracks are fitted with a straight line, $y = c + mx$
- Residual distribution of the tracks. (instead of χ^2/ndf distribution)
- Because the cosmic tracks mostly come from vertically, calculating the residual by perpendicular way is a better method.

Cosmic tracks event displays

Total clusters = 4, selected clusters = 4
Residual xy = 0.0046, residual zr = 0.0497

Total clusters = 7, selected clusters = 5
Residual xy = 0.0017, residual zr = 0.2849
