# New Metrics

## Peak Height Ratio (PHR)

$$\text{PHR} = \frac{|Max_{Tail}|}{|Max_{Main Peak}|}$$

- If PHR is Large → Significant Tail (relative to main peak).
- If PHR is Small → Weak Tail (relative to main peak).

## Tail Area Contribution (TAC)

$$\text{TAC} = \frac{|Area_{Tail}|}{|Area_{Main Peak}|}$$

- If TAC is Large → Tail contributes significantly to signal.
- If TAC is Small → Tail is a minor contribution to waveform.

## Baseline RMS ( $B_{rms}$ )

$$B_{rms} = \sqrt{\frac{1}{N} \sum_i (A_i - \bar{A})^2}$$

- $A_i$  = Bins before the main peak.
- $\bar{A}$  = Mean baseline ADC value.

The higher  $B_{rms}$ , the noisier the channel.

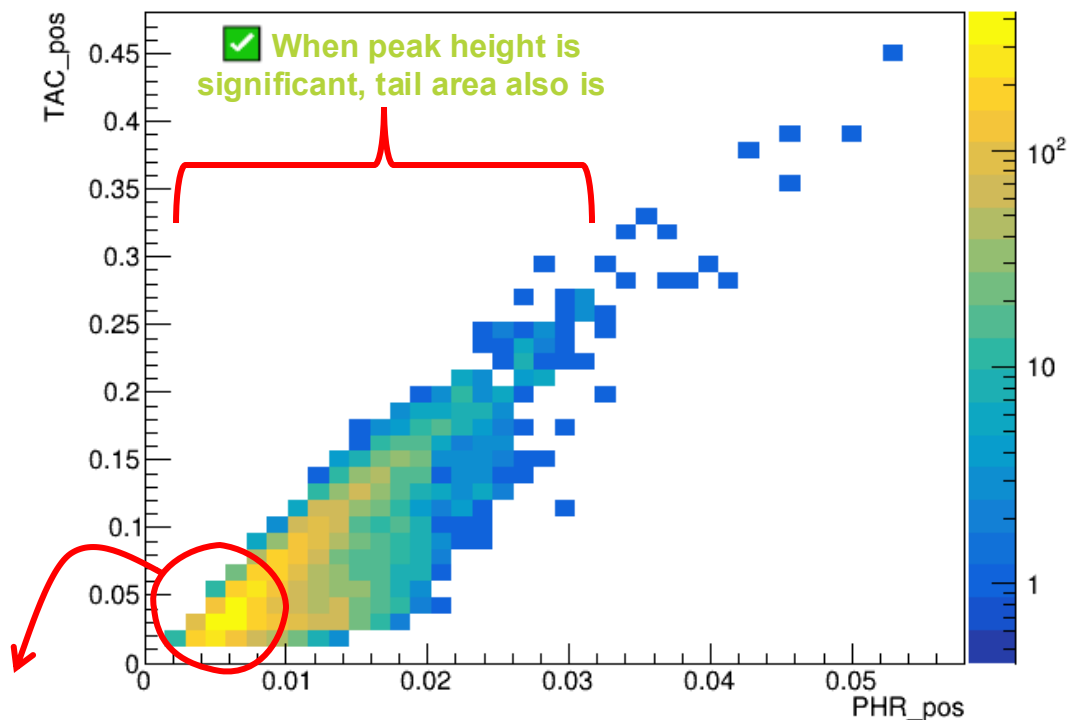

# Implementing these metrics on our data (single run)

*Looking for correlations amongst these metrics*

TAC vs. PHR for Positive Peak

✓ Most waveforms have small tails relative to their peaks

TAC vs. PHR for Negative Peak

✓ Wider spread but same positive correlation.
