# Using Deeply Virtual Compton Scattering to characterise the ePIC detector

Oliver Jevons  
University of Glasgow, UK

ePIC Collaboration Meeting  
23/01/25

WORLD  
CHANGING  
GLASGOW

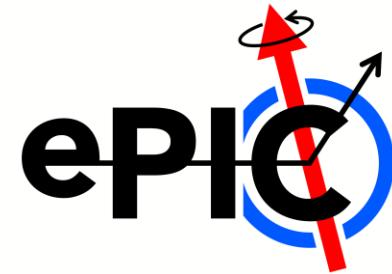

# This presentation

- Context: DVCS and its place in the EIC physics programme.
- Summary of simulation and analysis efforts.
  - Focus on 25.10.2 campaign output

University  
of Glasgow

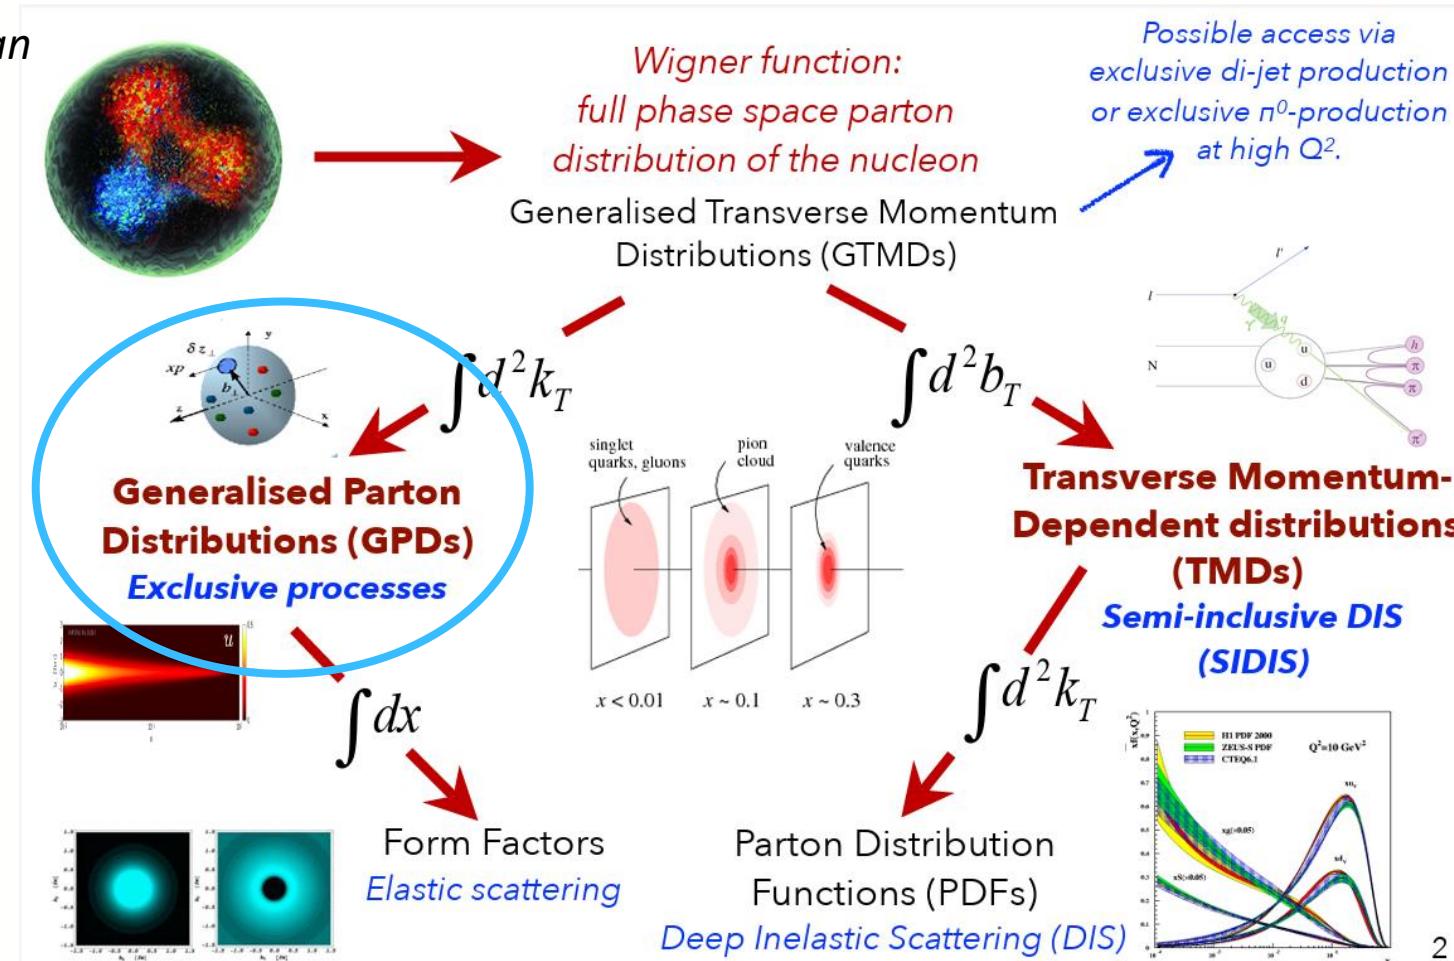

# Deeply Virtual Compton Scattering

# Nucleon structure – multi-dimensional pictures

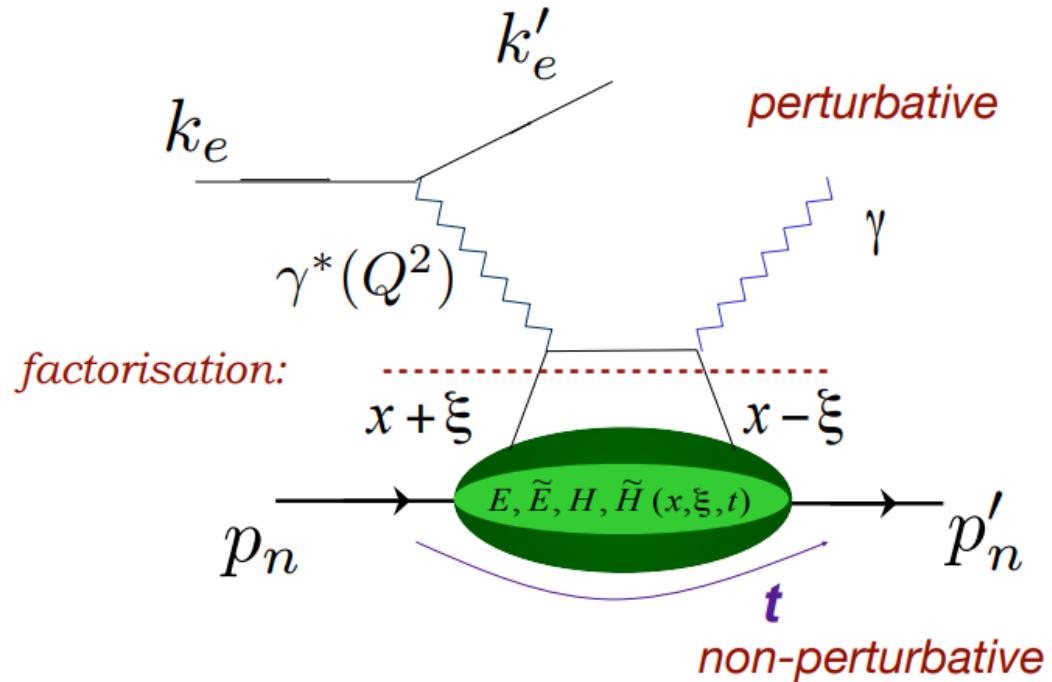

D. Sokhan

2

# Deeply Virtual Compton Scattering

- DVCS: electroproduction of a photon off a hadron target

- QM interference: Bethe-Heitler ( $e^-$  radiates final state photon).

# Deeply Virtual Compton Scattering: kinematics

- Default kinematics:

- $e(k) + p(p) \rightarrow e'(k') + p'(p') + \gamma$

- Inclusive kinematics: scattered electron only (“Electron method” in EICrecon)

$$Q^2 = -q^2 = -(k - k')^2 \quad y = \frac{q \cdot p}{k \cdot p} \quad x = \frac{Q^2}{2q \cdot p} \quad \xi = \frac{x}{2 - x} \approx \frac{x}{2}$$

- Mandelstam  $t$  (default): beam and scattered proton (BABE method in *t*RECO convention)

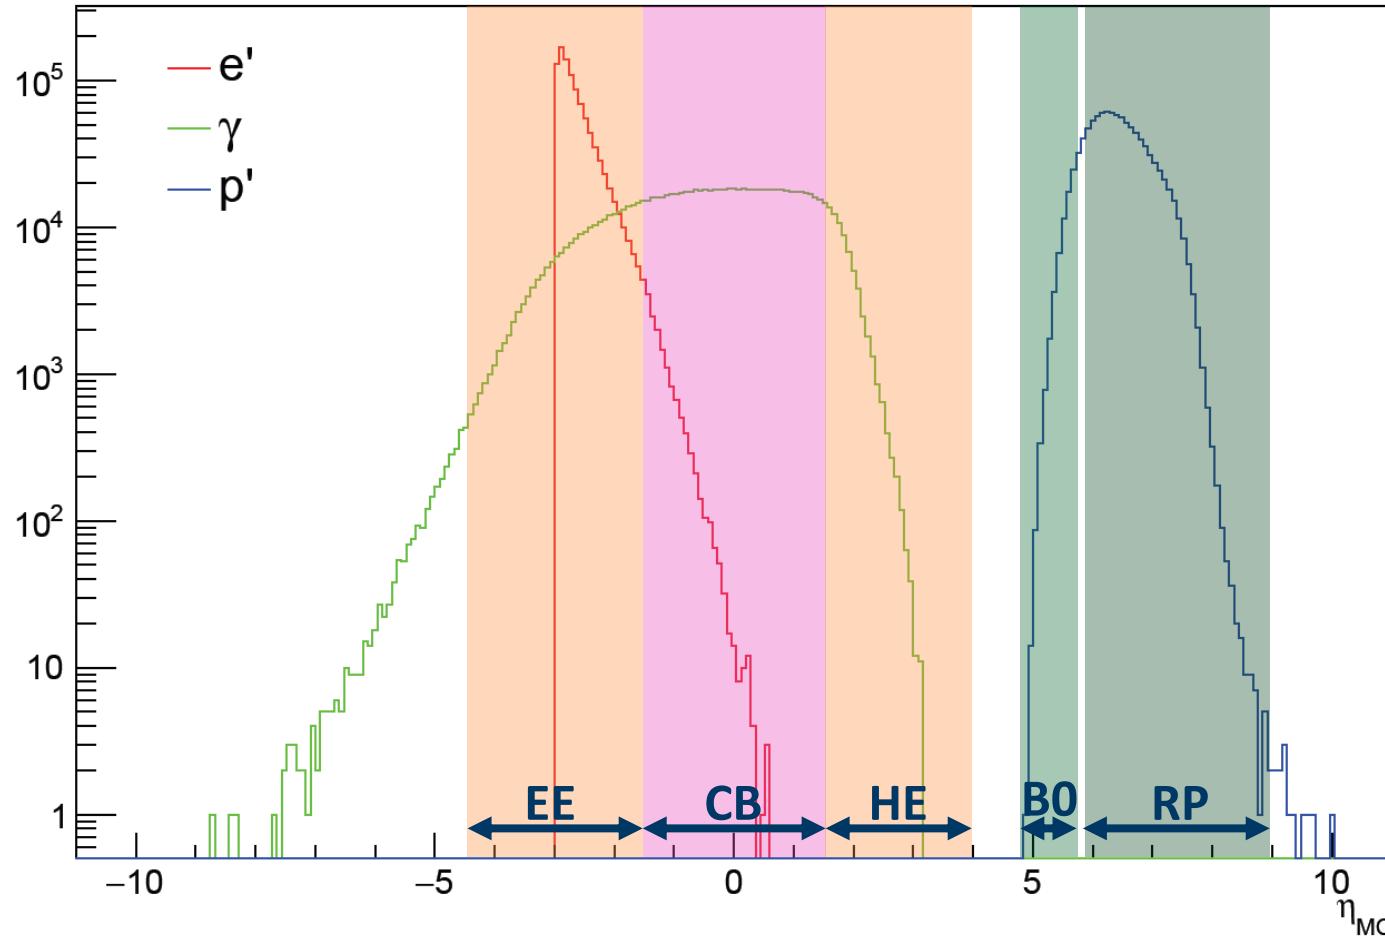

$$t = (p - p')^2$$

# Why DVCS @ ePIC?

- Amongst the EIC's physics goals are:
  - Probing the 3D structure of nucleons.
    - Fourier transform of GPDs.
  - Solving the mystery of proton spin.
    - Ji's Sum Rule (combination of GPDs)
- DVCS covers 2 of the stated physics goals in 1 channel!

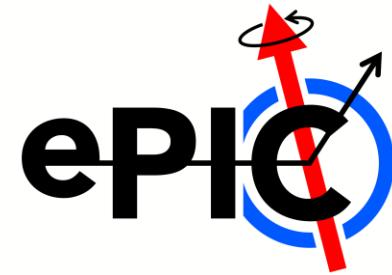

# Why DVCS @ ePIC?

- Much of the ePIC detector used for reconstruction.
  - Electrons: **central barrel** and **backward endcap**.
  - Photons: across **central barrel** and **both endcaps**.
  - Protons: **B0** and **Roman Pots** (energy-dependent).
    - 5x41 – 94% B0, 6% RP
    - 10x100 – 3% B0, 97% RP
    - 10x130 – same as 10x100
    - 18x275 – 100% RP

University  
of Glasgow

# DVCS simulations for ePIC

# Simulation details

- Using EplC generator ([GitHub link here](#)).
  - Purpose built generator for such GPD-sensitive processes (DVCS, TCS, DDVCS, etc.).
- Can run in fixed target or colliding beams mode.
  - Useful for JLab and EIC kinematics!
- DVCS<sup>[1]</sup>/BH<sup>[2]</sup> amplitudes (for samples used) from Belitsky and Mueller

[1] Belitsky, Mueller and Kirchner; Nucl. Phys. B **629** (2002); pp 323-392

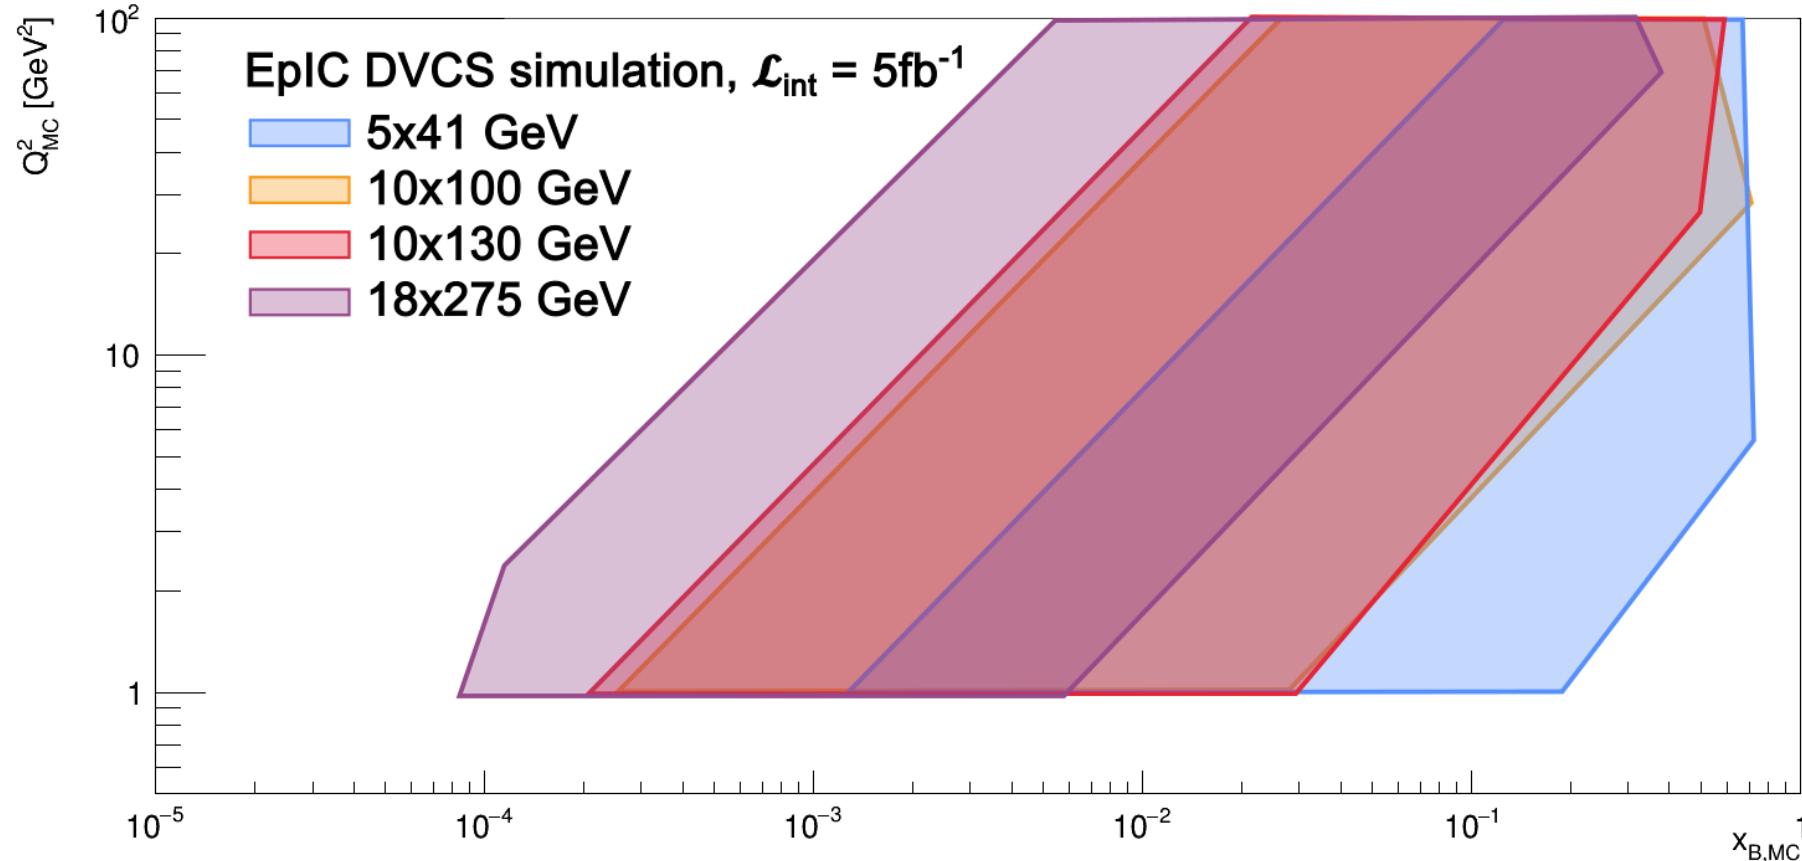

[2] Belitsky, Mueller and Ji; Nucl. Phys. B **878** (2014); pp 214-268

# Simulation details

- Current event samples used:
  - 1M events; DVCS only (5x41, 10x100, 18x275) / DVCS+BH+int. (10x130)
  - $1 < Q^2 < 100 \text{ GeV}^2$      $0.01 < y < 0.9$      $10^{-5} < x_B < 0.7$
- Generated events represent  $\mathcal{L}_{int} \sim 2 \text{ fb}^{-1}$  for the “standard” EIC energy settings,  $\mathcal{L}_{int} \sim 0.5 \text{ fb}^{-1}$  for 10x130 GeV.
- Events are passed through the full EIC simulation pipeline.
  - Afterburner (to add beam smearing and crossing angle).
  - npsim
  - EICrecon

# Coverage of generated data

# Analysis details

- MC information from `MCParticlesHeadOnFrameNoBeamFX`.
- Reconstructed particle PID using known Associations.
  - Scattered electron and photons reconstructed from tracker and calorimeter information.
  - Scattered protons in the B0 need truth seeding.
  - (For now) Assume all tracks from Roman Pots are real protons.
- Full afterburner removal based on procedure detailed by A. Jentsch in PWG meeting on 20<sup>th</sup> May 2024.

# Cuts applied

- Single species cuts:
  - Electron: only 1 reconstructed and  $Q^2 \geq 1 \text{ GeV}^2$
  - Photon: only 1 reconstructed
  - Proton: only 1 reconstructed and track theta appropriate for detector used.
    - $5.5 < \theta_p, < 20 \text{ mrad}$  for B0 tracks
    - $0 < \theta_p, < 5 \text{ mrad}$  for RP tracks
- DVCS event cuts:
  - Full exclusivity ( $e'p'\gamma$  reconstructed)
    - All single species cuts simultaneously.
  - $M_{miss}^2 \leq 1 \text{ GeV}^2$

# Detector acceptance correction

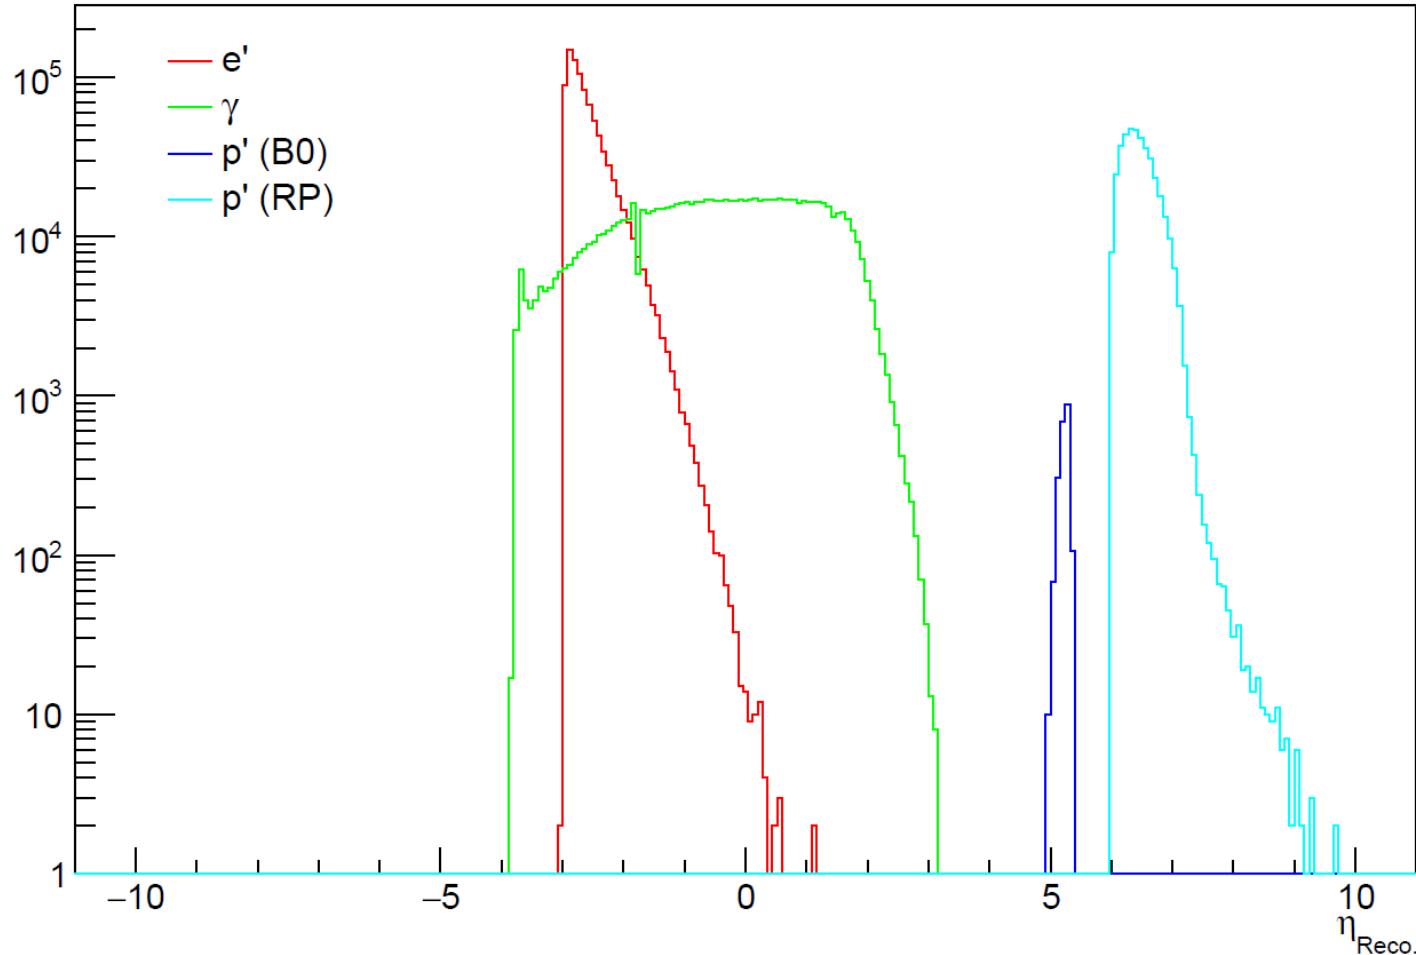

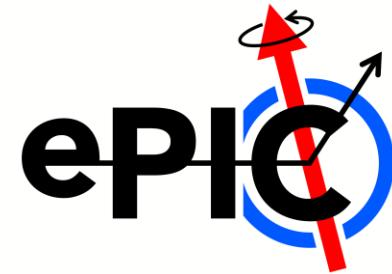

- Calculate acceptance from MC information if a reconstructed particle/event passes cuts.
  - Efficiency,  $\varepsilon = \frac{N(MC \text{ accepted})}{N(MC \text{ truth})}$
- Correct reconstructed distributions by efficiency.
  - $N(\text{corrected reco.}) = \frac{N(\text{raw reco.})}{\varepsilon}$
- Only correcting for detector acceptances for now.

# Analysis output

Results shown are based on 25.10.2 campaign  
Using 10x100 GeV as example, scaled to 5  $\text{fb}^{-1}$

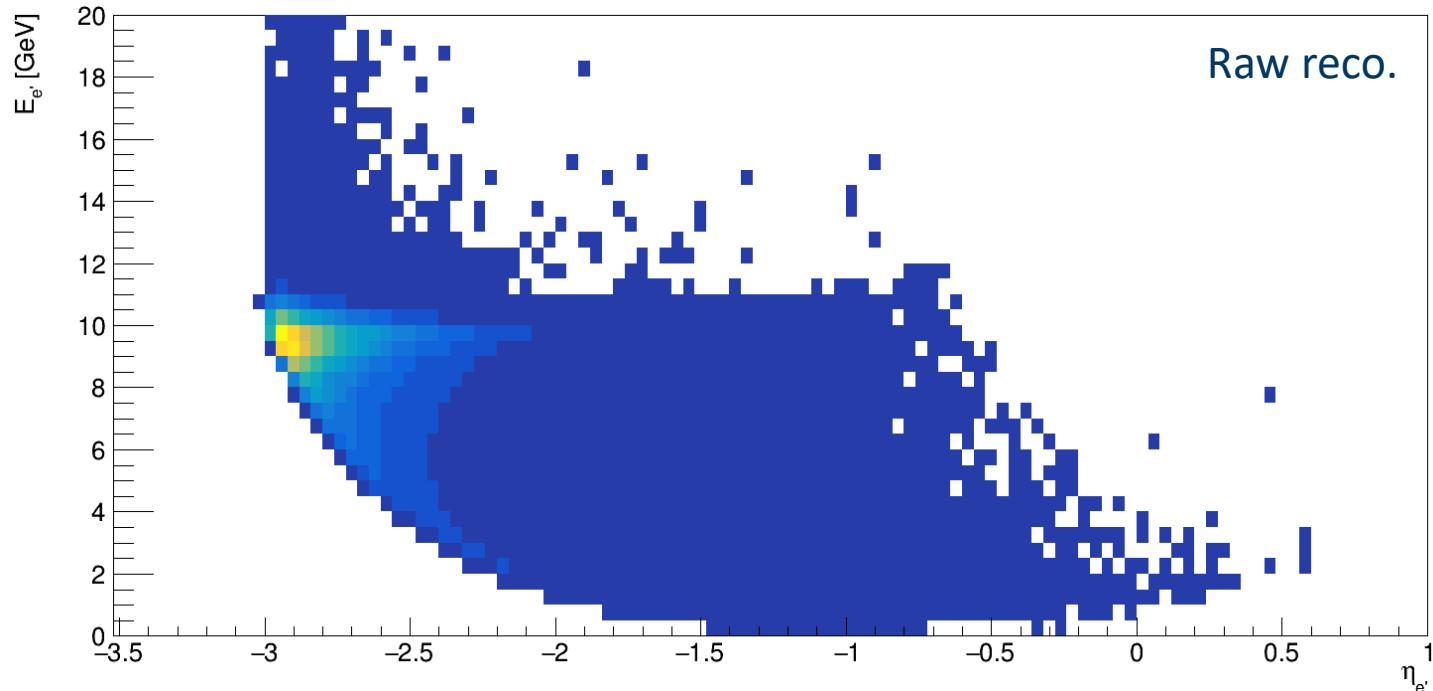

# All final state particles (10x100)

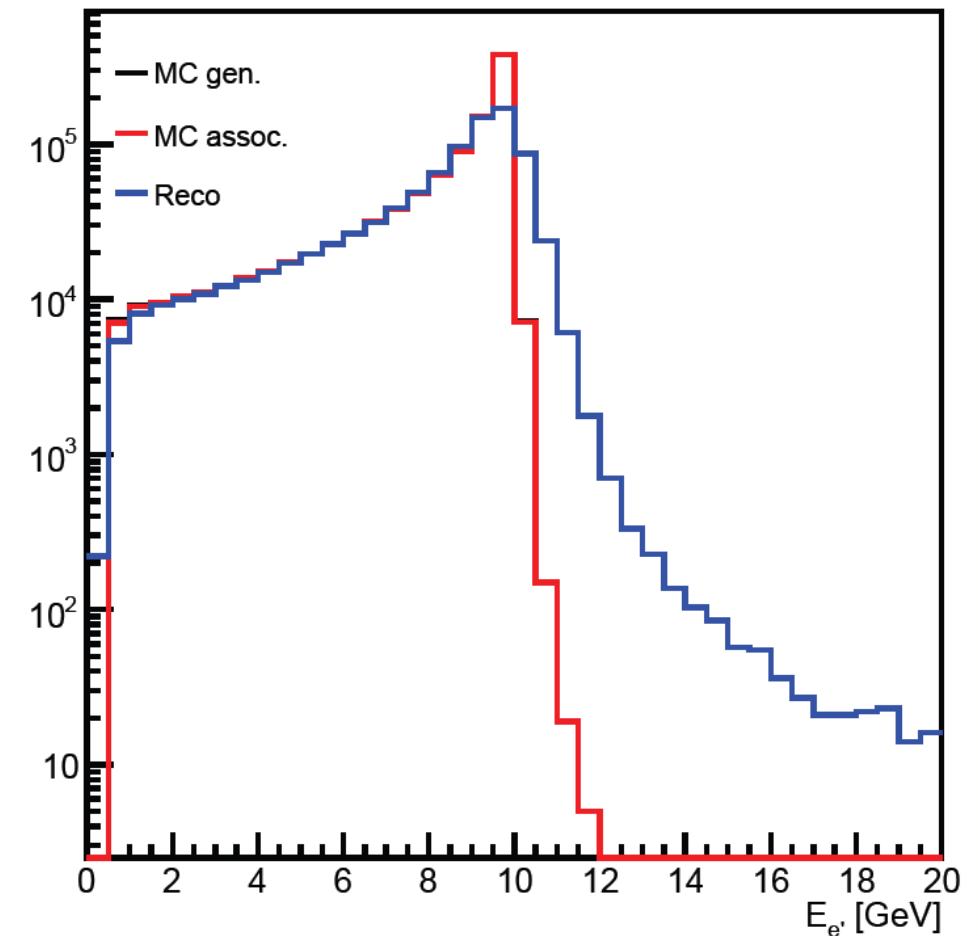

- Some overlap between final state species ( $e'/\gamma$ ), but easily separated by charge.
- Clean detector signatures.

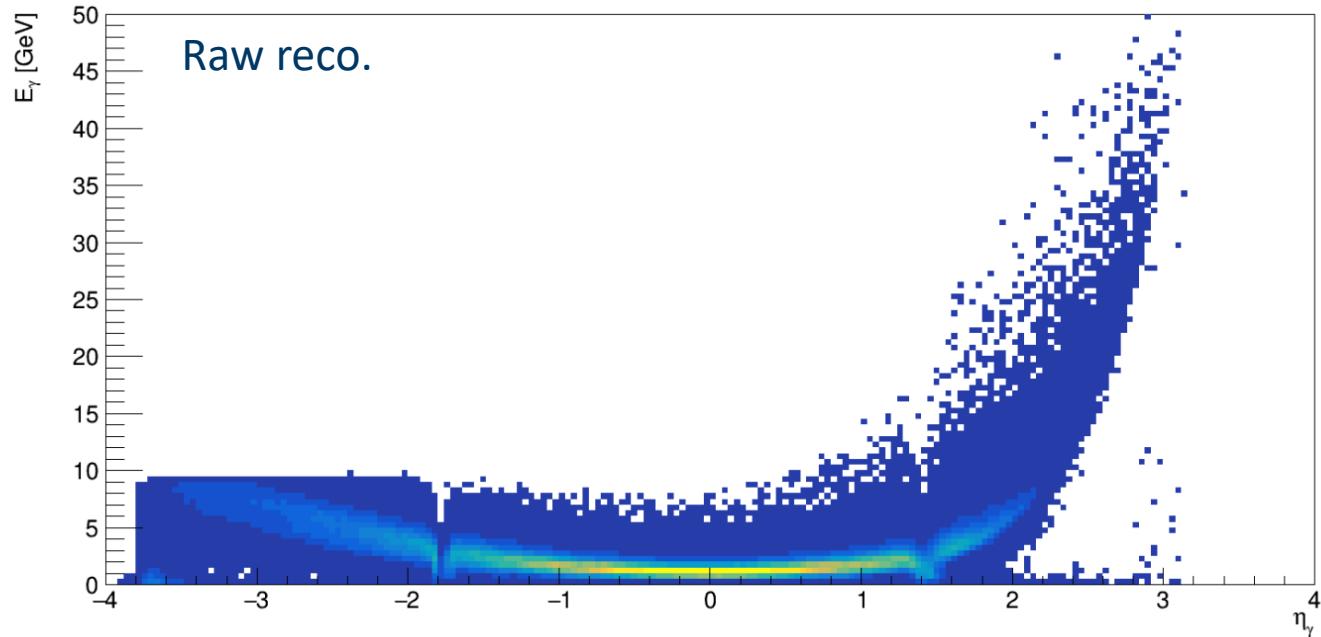

# Scattered electrons

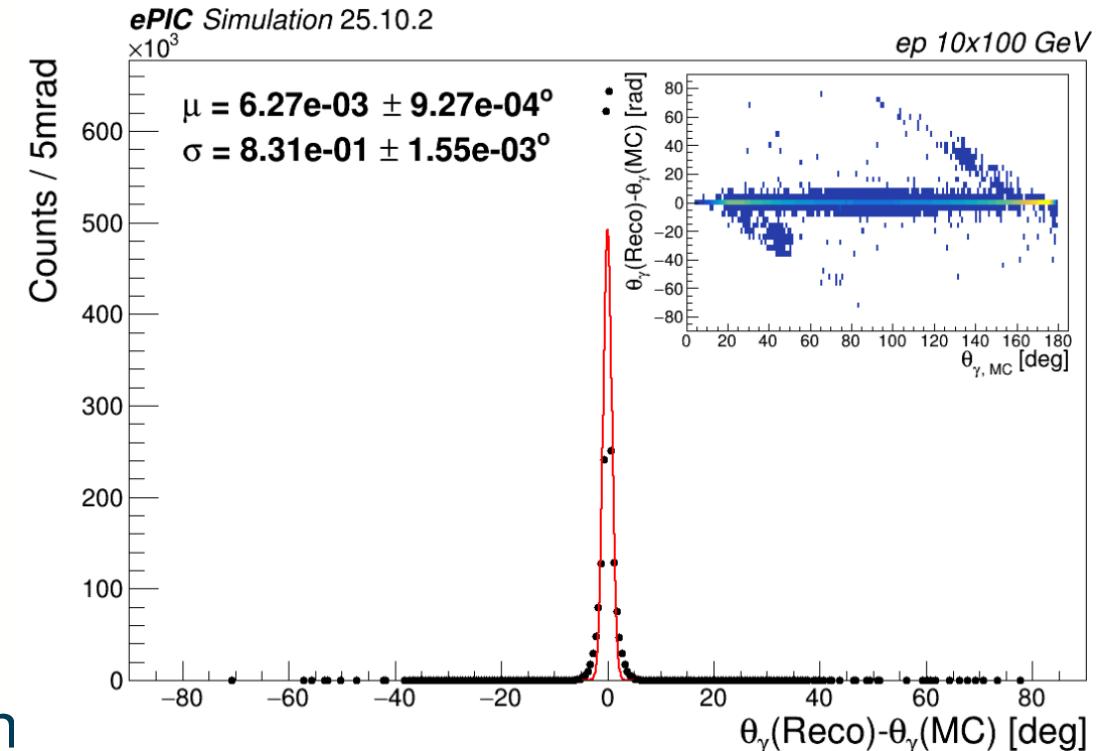

- Most at inner edge of backward ECAL.
- Noticeable smearing, particularly at higher momenta.

# Real photons

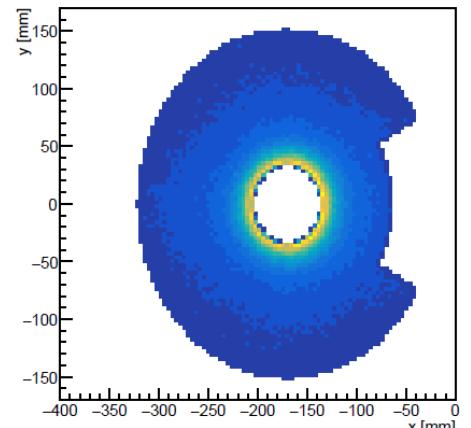

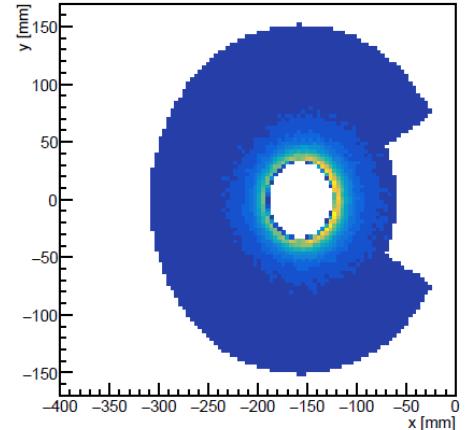

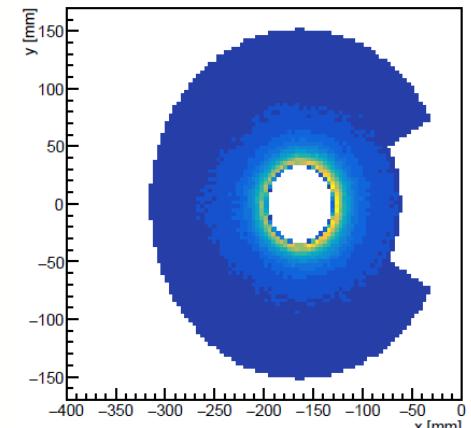

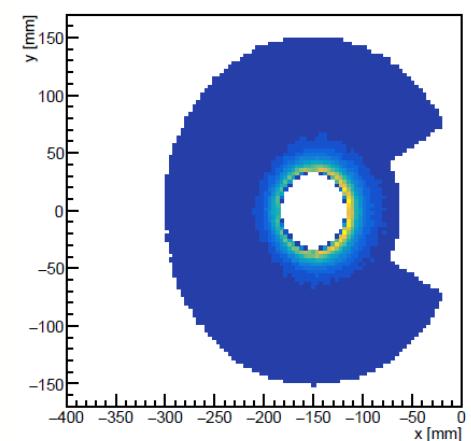

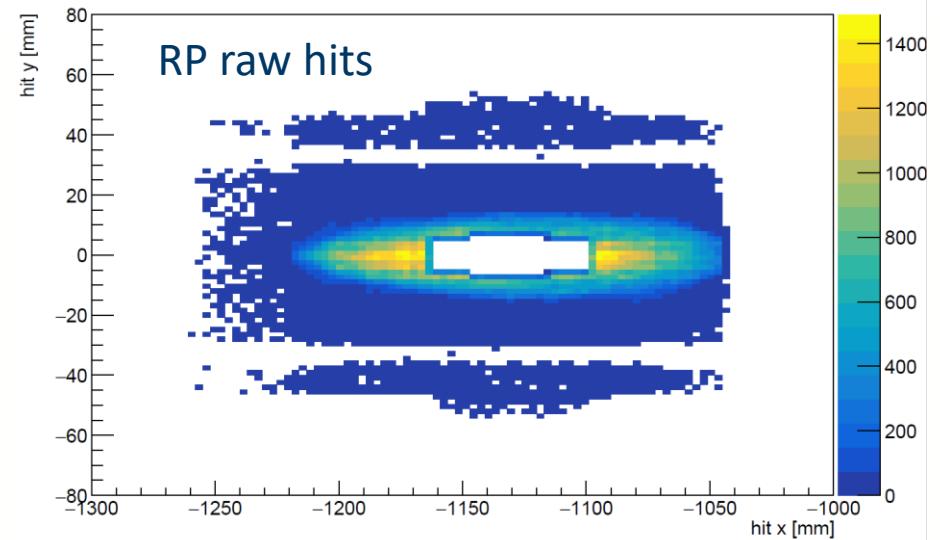

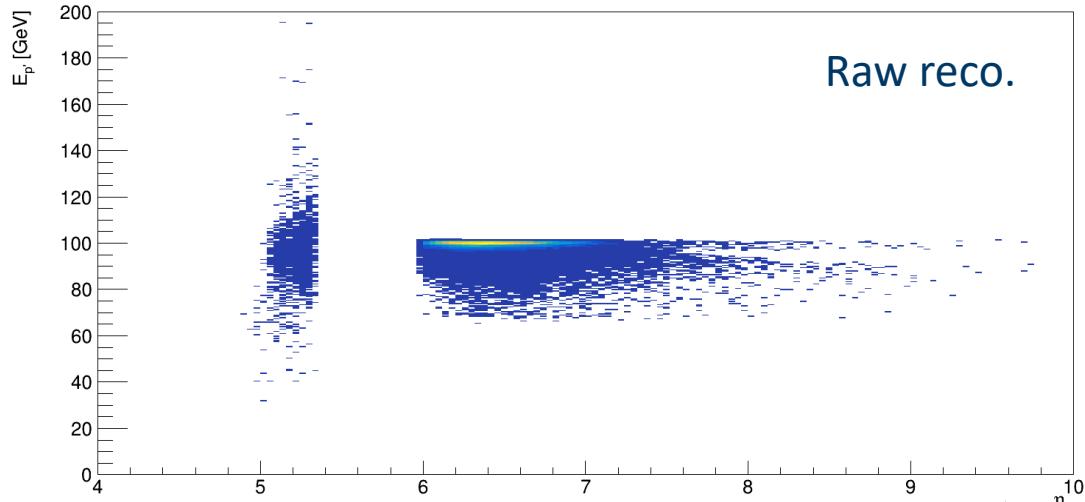

- ~20% in backwards endcap ( $\eta < -1.7$ ), ~70% in central barrel ( $-1.7 \leq \eta \leq 1.4$ ), ~10% in forward endcap ( $\eta > 1$ ).

# Scattered protons

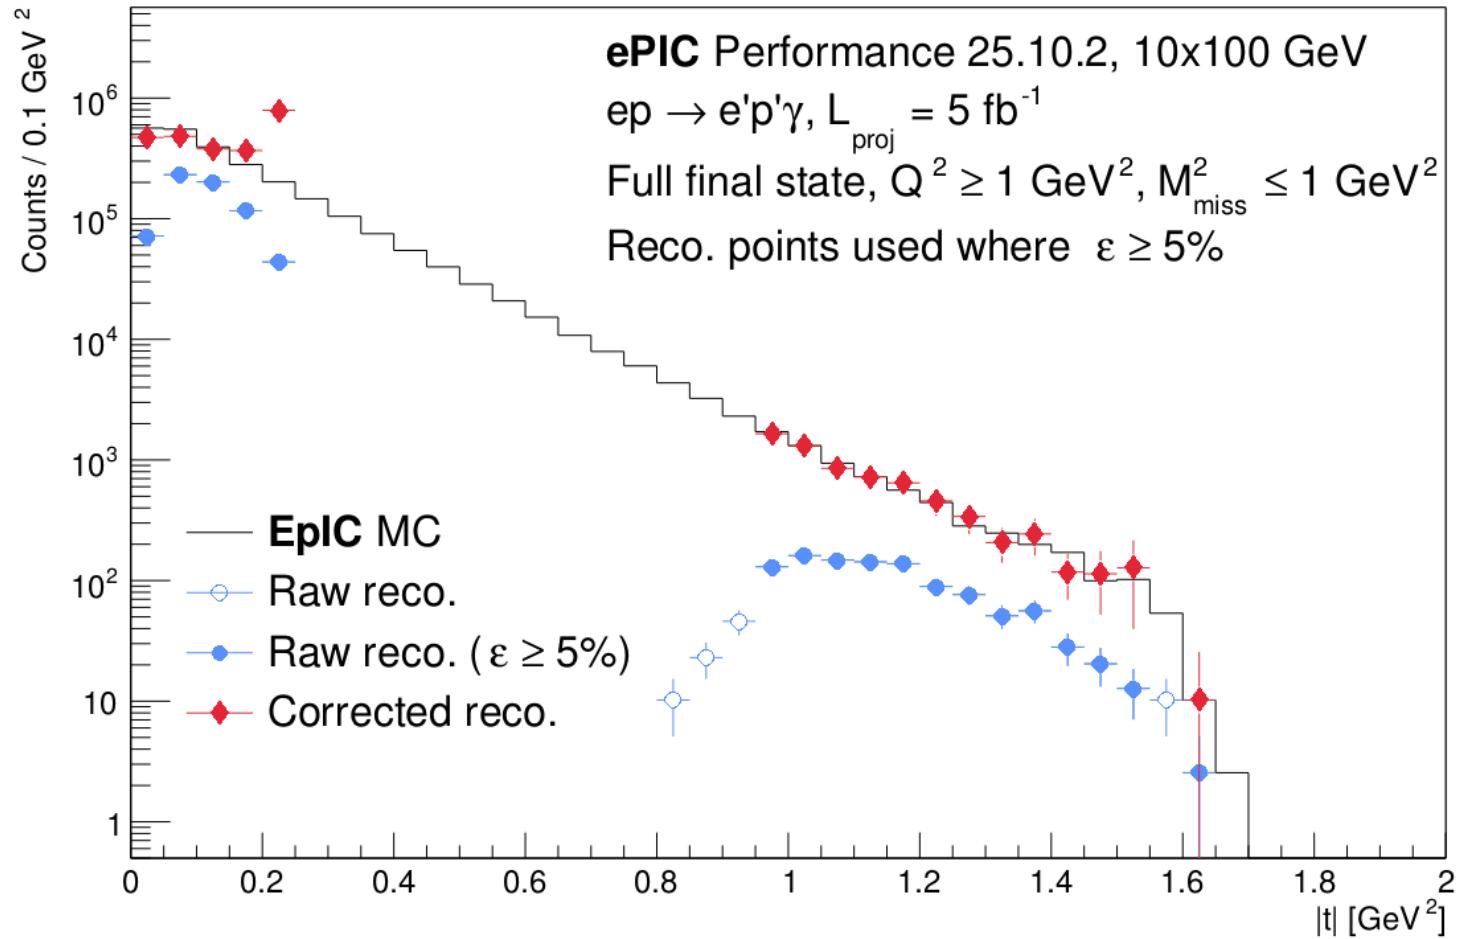

# Full DVCS events

- All cuts applied:
  - Full exclusivity (1x electron, 1x photon, 1x proton)
  - Full final state missing mass,  $M_{miss}^2 \leq 1 \text{ GeV}^2$
- Effect of cuts (sample of  $\sim 10k$  generated events):
  - All events: 10439
  - Full exclusivity: 4182 ( $\sim 40\%$ )
    - 1x  $e'$ : 10237 ( $\sim 98\%$ )
    - 1x  $\gamma$ : 9820 ( $\sim 94\%$ )
    - 1x  $p'$ : 4486 ( $\sim 43\%$ )
  - ...with  $\theta_p$  cut: 3882 ( $\sim 37\%$ )
  - ...with  $Q^2$  cut: 3522 ( $\sim 33\%$ )
  - ...with  $MM^2$  cut: 3165 ( $\sim 30\%$ )

Still limited by proton acceptance,  
but far less than before.

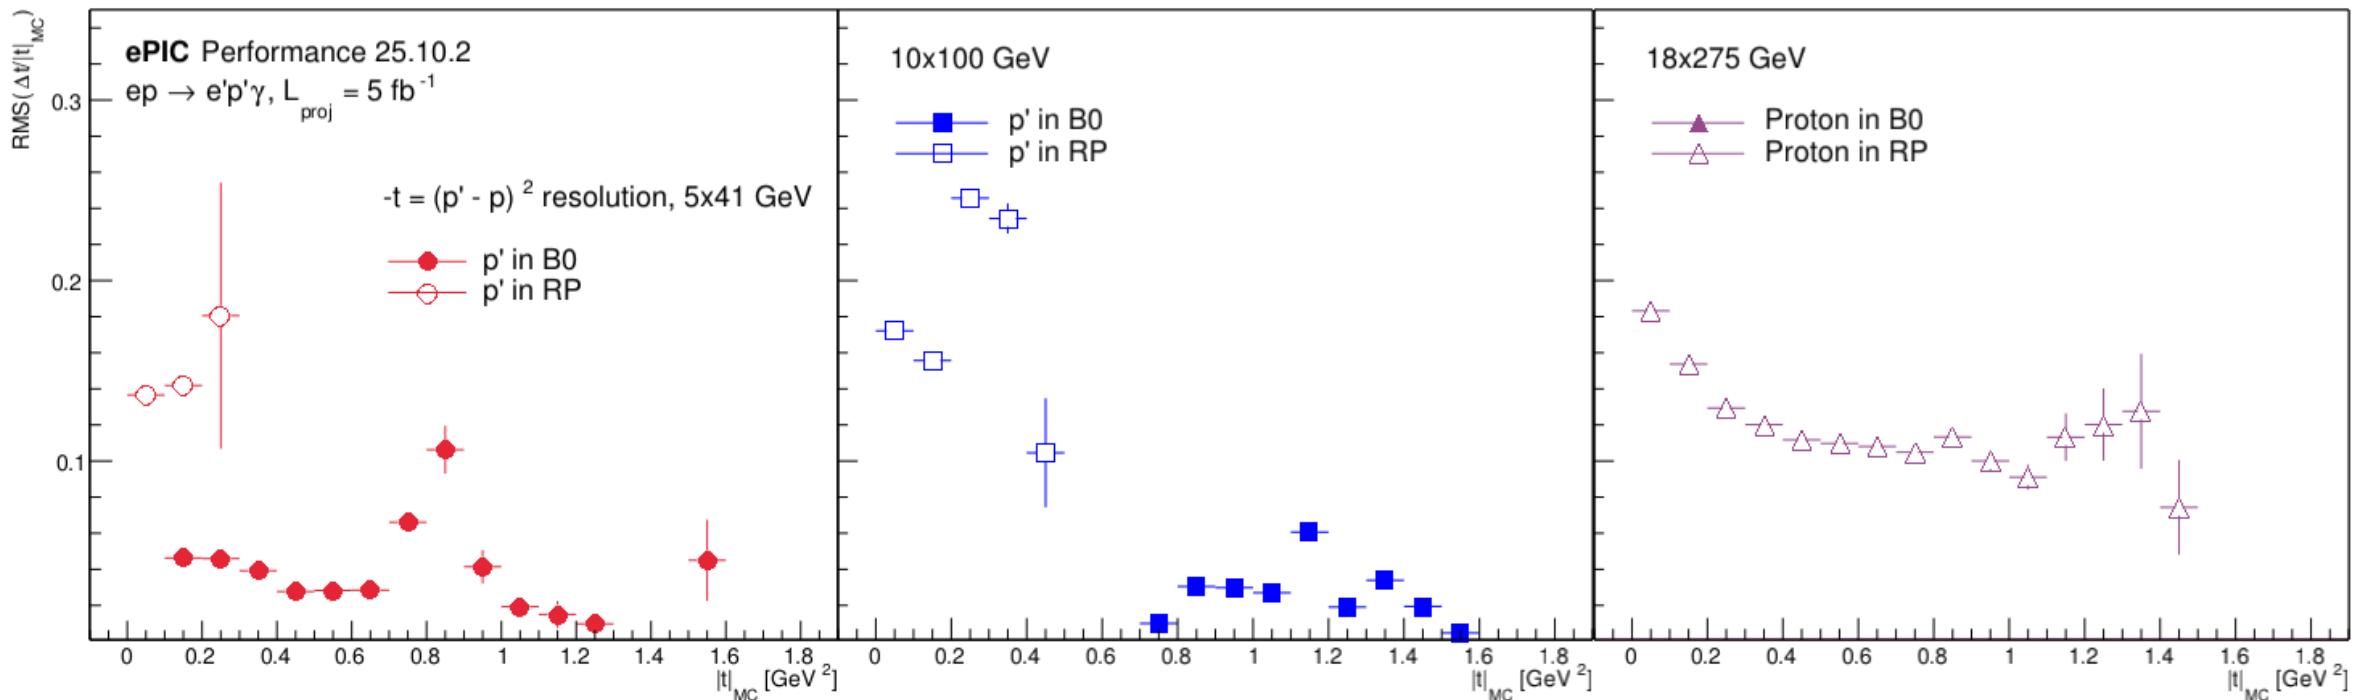

# Calculation of Mandelstam $t$ – full DVCS events

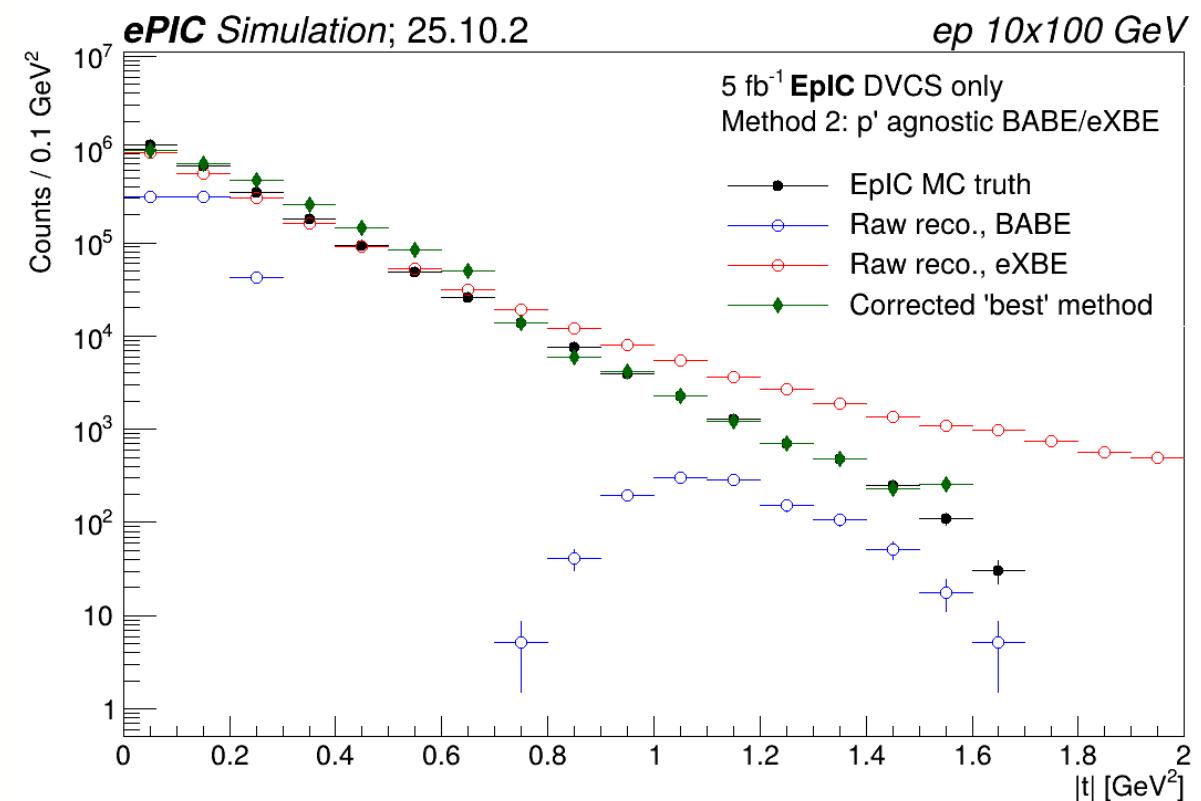

# Mandelstam $t$ resolution

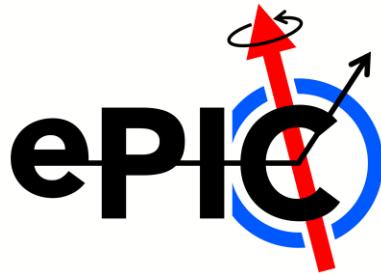

# Alternative calculations for $t$

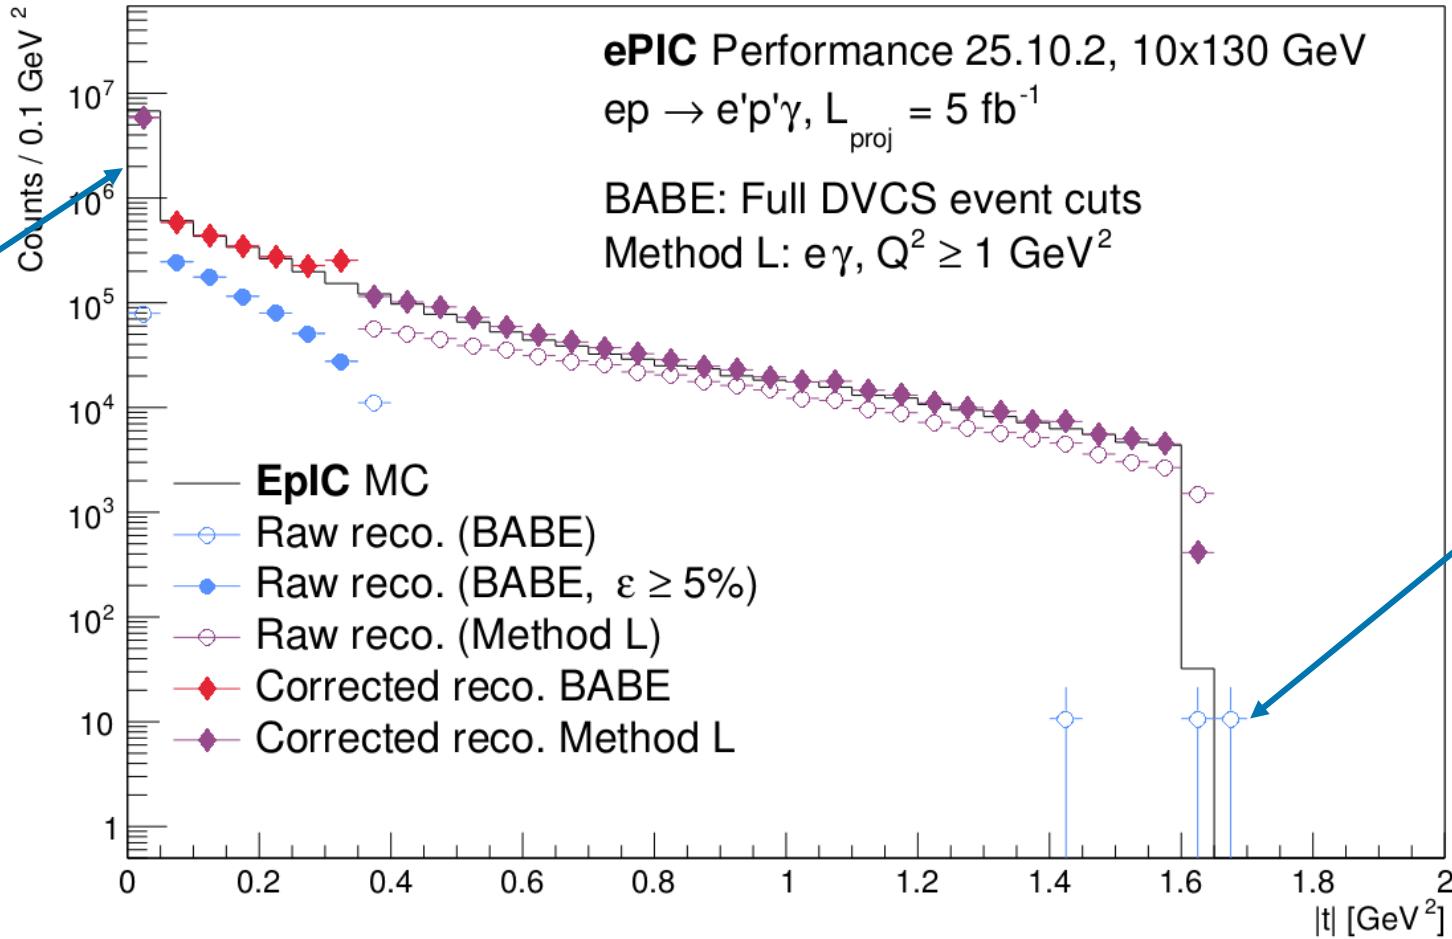

- Alternative methods for calculating Mandelstam  $t$  have been proposed but never seem to have worked for the DVCS simulation data.
- Had decided on using ‘eXBE’ method (tRECO) from looking at behaviour of MC.
  - This method overshoots the MC distribution at higher  $t$ .
- Need to make new choice: use ‘Method L’ (as for DV $\pi^0 P$ ).
  - Still only works for 10x130 data.
  - Issue in older data makes semi-inclusive calculations fail.

# Calculation of Mandelstam $t$ – 10x130

Low- $t$  peak from inclusion of Bethe-Heitler events in 10x130 sample.

Loss of reconstruction for B0 protons since 25.07.0 campaign.

Due to change in ACTS behaviour.

Fix expected in most recent campaign – have not yet had a chance to test this.

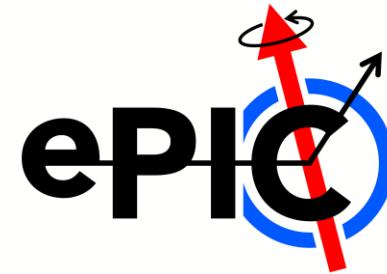

# New EpIC MC samples

- New DVCS event samples have been generated and are now being tested locally on the Glasgow systems.
  - 1M events (5x41, 10x250, 18x275) / 1.3M events (10x100, 10x130)
  - 2 helicity settings for each energy (2/2.6M events total per energy)
  - Using EpIC v1.1.6
- When these have been verified, they will be used for future simulation campaigns.
  - Can now start looking at asymmetries.
  - Fixed t calculations without the proton.

# Concluding remarks

# Summary

- i. Efforts ongoing with looking at DVCS simulations with ePIC.
  - Extraction of  $d\sigma/dt$  possible.
- ii. Newer MC samples are available and will replace the current simulation campaigns.
  - 2x e-beam helicity settings to study asymmetries.
  - Fixed calculation of Mandelstam  $t$  when ignoring the proton.
  - Now including 10x250 ep energy setting for early science studies.

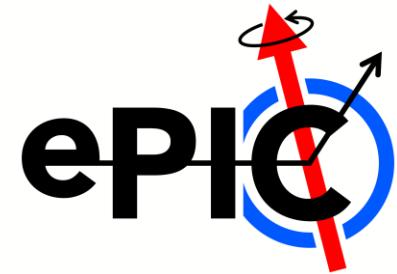

# Thank you for listening!

Any questions?

# Nucleon structure

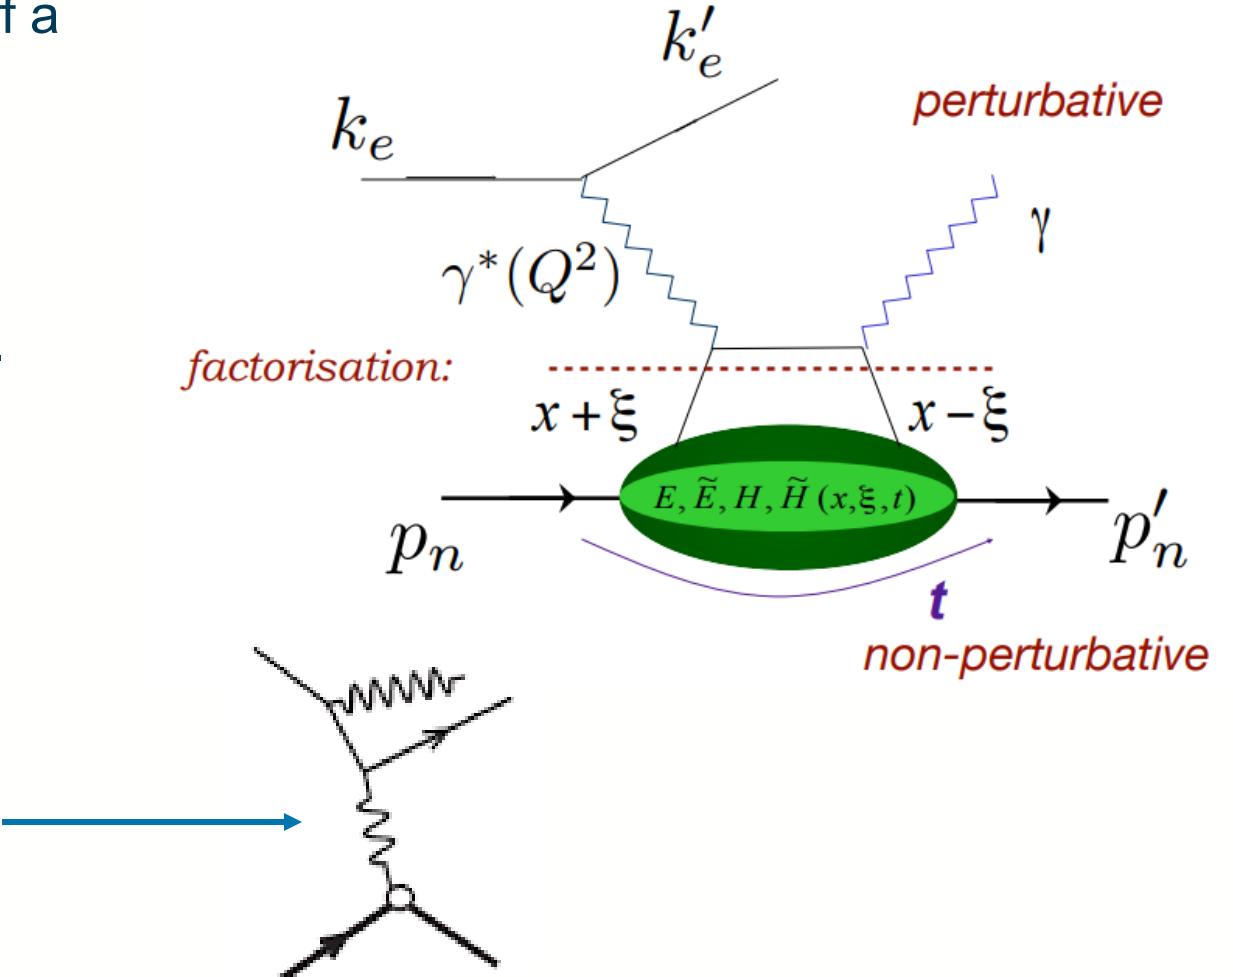

D. Sokhan

- Nucleon structure can be described within multiple dimensions by a large number of different functions.
  - GTMDs – full 5D phase space distributions.
  - PDFs – 1D as function of parton momentum.
  - Form factors – 1D as function of transverse distance from centre.
- GPDs relate the transverse position of partons to their longitudinal momentum fraction.

# Deeply Virtual Compton Scattering

- Electroproduction of a single photon off a hadron target.
  - $ep \rightarrow e'p'\gamma$
  - Simplest inelastic channel the EIC can study.
  - Easiest channel for probing GPDs.
- The cross-section for this process is related to its matrix element,  $|\mathcal{T}|^2$ .
  - $|\mathcal{T}|^2 = |\mathcal{T}_{DVCS}|^2 + |\mathcal{T}_{BH}|^2 + \mathcal{I}$
  - $\mathcal{I}$  is an interference term.
  - Bethe-Heitler: purely EM process, which does not probe partonic content.

# Deeply Virtual Compton Scattering

- Default kinematics:

- $e(k) + p(p) \rightarrow e'(k') + p'(p') + \gamma$

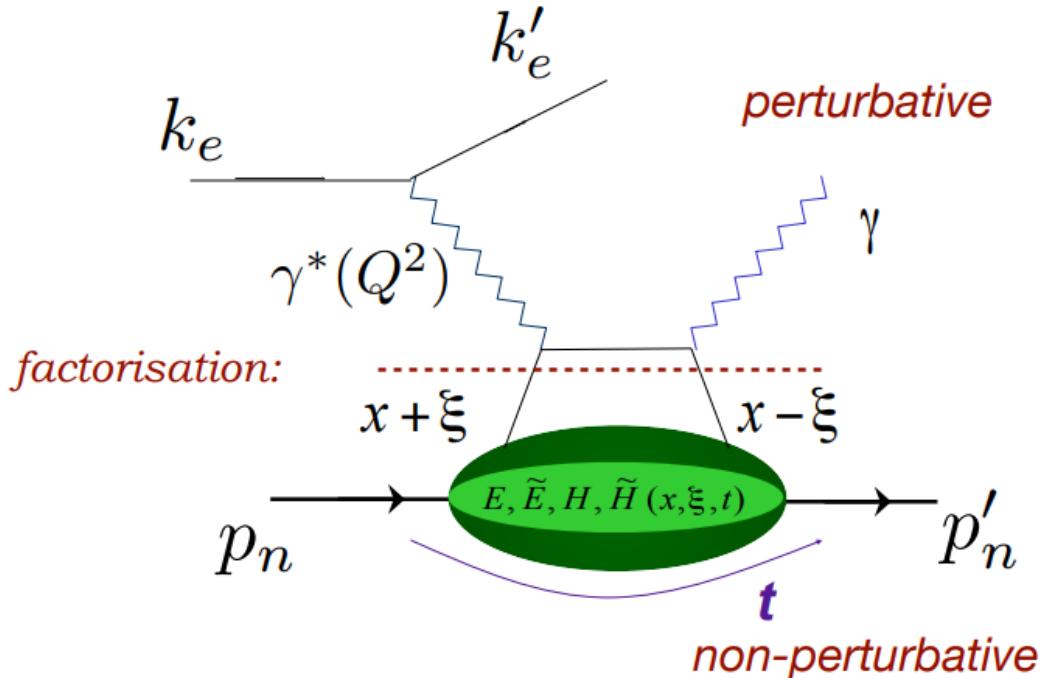

$$Q^2 = -q^2 = -(k - k')^2 \quad x = \frac{Q^2}{2q \cdot p}$$

$$y = \frac{q \cdot p}{k \cdot p}$$

$$\xi = \frac{x}{2 - x} \approx \frac{x}{2}$$

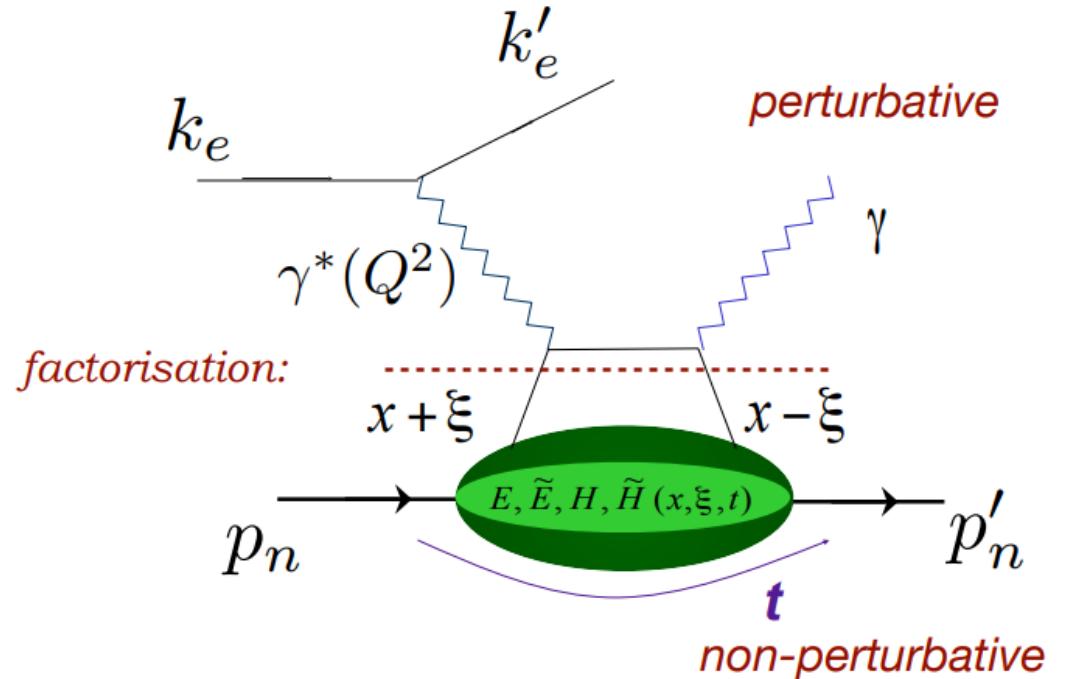

$$t = (p - p')^2$$

- Other formulae exist, using other combinations of reconstructed quantities, if needed (e.g. see InclusiveKinematics branches in EICrecon trees).

# Deeply Virtual Compton Scattering

- DVCS amplitude can be parameterized in terms of Compton Form Factors (CFFs).
  - Experimentally accessible!
  - Access 4 quark GPDs:  $H_q, \tilde{H}_q, E_q, \tilde{E}_q$ .
  - Note: does not access GPDs directly, but linear combinations of GPDs.
- $Re \mathcal{F}_q(\xi, t) \propto \int_0^1 [F_q(x, \xi, t) - F_q(-x, \xi, t)] dx$
- $Im \mathcal{F}_q(\xi, t) \propto [F_q(\xi, \xi, t) - F_q(-\xi, \xi, t)]$
- Different combinations of (un)polarised beam and target are sensitive to different combinations of CFFs.

Extract CFFs from asymmetries between different beam polarisation states!

# Why DVCS @ ePIC?

- Amongst the EIC's physics goals are:
  - Probing the 3D structure of nucleons.
  - Solving the mystery of proton spin.
- For an unpolarised target, the distribution of unpolarised quarks is the Fourier transform of the GPD  $H_q$ .

$$q(x, b_\perp) = \int \frac{d^2 \Delta_\perp}{(2\pi)^2} e^{-ib_\perp \Delta_\perp} H_q(x, 0, t = -\Delta_\perp^2)$$

# Why DVCS @ ePIC?

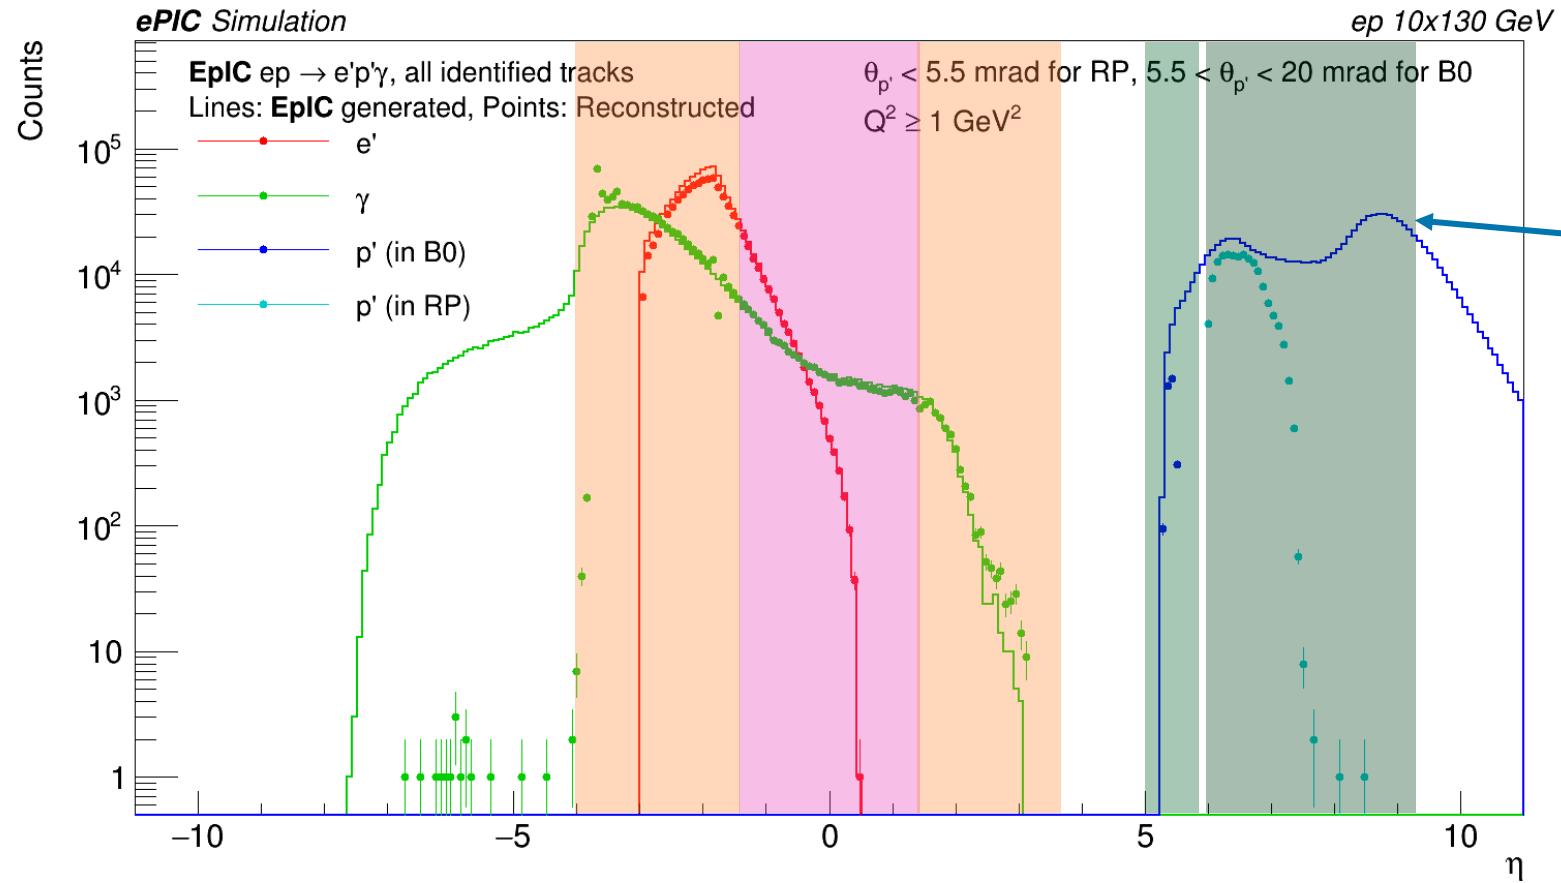

- Amongst the EIC's physics goals are:
  - Probing the 3D structure of nucleons.
  - Solving the mystery of proton spin.
- By Ji's Sum Rule, quark angular momentum can be given by a combination of GPDs.

$$J = \frac{1}{2} \int_{-1}^1 x dx [H(x, \xi, t = 0) + E(x, \xi, t = 0)]$$

# Why DVCS @ ePIC?

- The final state of the DVCS reaction will utilise many of the subsystems present in ePIC and provide useful probes of their resolutions.
  - The **scattered proton** will only be deflected by a small angle and will end up in the **far forward** region.
    - Tests B0 spectrometer and Roman Pots.
  - The **scattered electron** will be detected in the **central barrel** or (mostly) the **backward endcap**.
    - Test of trackers, PID detectors and calorimeters almost everywhere in the barrel (just not hadron endcap/planes).
  - The **scattered photon** will be detected in the **backward endcap**.
    - Very clean test of EEMCAL resolution.

# Detector occupancy (10x130)

Lot of BH  
background is  
removed by RP  
acceptance!

# Analysis details

Analysis code [on GitHub](#).

# Analysis details

- Truth level particles in MCParticles branch.
  - Truth level with PID – afterburner applied.
- Reconstructed electrons and photons in ReconstructedParticles branch.
  - ePIC PID not accurate – using ReconstructedParticleAssociations to select candidates.
  - Electron energy is calculated using given momenta and  $e^-$  mass.
  - Associations branch also used for MC acceptance.

# Analysis details

- Reconstructed protons in the B0 detector taken from `ReconstructedTruthSeededChargedParticles` branch.
  - Corresponding `Associations` branch used for PID.
  - Energy calculated from momentum and proton mass.
  - `Associations` also used for MC acceptance.
- Reconstructed protons in Roman Pots taken from tracks in `ForwardRomanPotRecParticles` branch.
  - All tracks in RP branch assumed to be protons.
  - If RP track is present, assume that MC proton is the correct associated particle.
