

A light 0^{++} and other hadronic resonance from a new strongly interacting sector exhibiting large scale separation

Oliver Witzel

University of Colorado
Boulder

Brookhaven Forum 2017
Upton, NY, October 11, 2017

based on

R. Brower, A. Hasenfratz, C. Rebbi, E. Weinberg, O.W. PRD 93 (2016) 075028

A. Hasenfratz, C. Rebbi, O.W. PLB 773C (2017) 86-90

Motivation

- ▶ Mass of the Higgs boson is 125 GeV
 - ▶ Other states must be much heavier, likely > 1.5 TeV
 - ▶ Standard Model not UV complete
 - ▶ What is the origin of the electro-weak sector?
- ⇒ Seek a model exhibiting a large separation of scales
- ↪ Near-conformal gauge theories / composite Higgs model

Near-conformal gauge theories

- ▶ Gauge-fermion system with $N_c \geq 2$ colors and N_f flavors in some representation
- ▶ Using perturbative 2-loop results as guidance

Composite Higgs models

- ▶ New, strongly interacting gauge fermion system
- ▶ Effective theory describing part of the dynamics
- ▶ Coupled to the Standard Model

Higgs-less, massless SM \rightarrow “full” SM

$$\mathcal{L}_{UV} \rightarrow \mathcal{L}_{SD} + \mathcal{L}_{SM_0} + \mathcal{L}_{int} \rightarrow \mathcal{L}_{SM} + \dots$$

Composite Higgs models

- ▶ New, strongly interacting gauge fermion system
- ▶ Effective theory describing part of the dynamics
- ▶ Coupled to the Standard Model

Add new strong dynamics coupled to SM

$$\mathcal{L}_{UV} \rightarrow \mathcal{L}_{SD} + \mathcal{L}_{SM_0} + \mathcal{L}_{int} \rightarrow \mathcal{L}_{SM} + \dots$$

Full SM + states from \mathcal{L}_{SD}

This construction gives mass to:

- ▶ the SM gauge fields
- ▶ the SM fermions fields: 4-fermion interaction or partial compositeness

Composite Higgs models

- ▶ New, strongly interacting gauge fermion system
- ▶ Effective theory describing part of the dynamics
- ▶ Coupled to the Standard Model

$$\mathcal{L}_{UV} \rightarrow \mathcal{L}_{SD} + \mathcal{L}_{SM_0} + \mathcal{L}_{int} \rightarrow \mathcal{L}_{SM} + \dots$$

Full SM + states from \mathcal{L}_{SD}

This construction gives mass to:

- ▶ the SM gauge fields
- ▶ the SM fermions fields: 4-fermion interaction or partial compositeness

Does not explain mass of \mathcal{L}_{SD} fermions and 4-fermion interactions: \mathcal{L}_{UV}

Candidates for \mathcal{L}_{SD}

- ▶ Promising candidates are chirally broken in the IR but conformal in the UV
[Luty and Okui JHEP 09(2006)070], [Dietrich and Sannino PRD75(2007)085018],
[Vecchi arXiv:1506.00623], [Ferretti and Karateev JHEP 1403 (2014) 077], . . .
- ▶ SU(3) gauge theory with **4 light** (massless) and **8 heavy** fundamental flavors

- ▶ Add 8 “heavy” fundamental flavors
- ▶ $N_f = 4 + 8 = 12$: conformal dynamics
- ▶ SU(3) gauge theory with 4 light flavors
- ▶ Chirally broken in the IR

↪ 4, 8, 12 are preferred for simulations with unrooted staggered fermions

→ “Walking” gauge coupling, tunable by changing m_h

→ Anomalous dimensions correspond to the conformal IRFP

→ Model features both pNGB or dilaton-Higgs scenarios

Two possibilities for a composite Higgs (IR sector)

▶ Spontaneous breaking of **scale** symmetry: Higgs is a dilaton

- Possibly light 0^{++} scalar
- $F_\pi = \text{SM vev} \sim 246 \text{ GeV}$
- ideal 2 massless flavors in the IR
- closer to old technicolor ideas

▶ Spontaneous breaking of **flavor** symmetry: Higgs is a pNGB

- Mass emerges from its interactions
- Non-trivial vacuum alignment $F_\pi = (\text{SM vev})/\sin(\chi) > 246 \text{ GeV}$
- ideal 4 massless flavors in the IR
- Vecchi: UV-complete models requiring at least two types of fermions in two different gauge group representations [arXiv:1506.00623]
- Ferretti: Classification of models with custodial symmetry and partial compositeness [JHEP 1403 (2014) 077] [JHEP 1606 (2016) 107]
- Ma and Cacciapaglia: Fundamental composite 2HDM with 4 flavors in SU(3) gauge [JHEP 03 (2016) 211]

Implementation on the lattice

- ▶ Choose N_f flavors above the conformal window
- ▶ Split the masses: $N_f = N_\ell + N_h$
 - ▶ N_ℓ flavors are massless, extrapolate $m_\ell \rightarrow 0 \Rightarrow$ chirally broken
 - ▶ N_h flavors are massive, we will vary $m_h \rightarrow$ decouple in the IR
 - \rightarrow Choose m_h to feel the attraction of the IRFP of $N_f = 12$

- ▶ We have 3 parameters:
 - $\rightarrow g$ irrelevant coupling
 - $\rightarrow m_\ell \rightarrow 0$ (chiral limit)
 - $\rightarrow m_h$: sets the scale

Derivation of hyperscaling from Wilson RG

► Scale change: $\mu \rightarrow \mu' = \mu/b$, with $b > 1$

⇒ bare masses increase:

$$\widehat{m}(\mu) \rightarrow \widehat{m}(\mu') = b^{y_m} \widehat{m}(\mu)$$

⇒ bare coupling approaches its fixed point:

$$g \rightarrow g^*$$

⇒ any 2-point correlator:

$$C_H(t; g, \widehat{m}, \mu) \rightarrow b^{-2y_H} C_H(t/b; g_i^*, b^{y_m} \widehat{m}, \mu)$$

► Now $C_H(t) \propto \exp(-M_H t) \Rightarrow aM_H \propto (\widehat{m})^{1/y_m}$ (hyperscaling)

► Likewise amplitudes (F_π) show hyperscaling $\Rightarrow M_H/F_\pi$ are constant

[Del Debbio and Zwicky PRD82 (2010) 014502][PLB 734 (2014) 107]

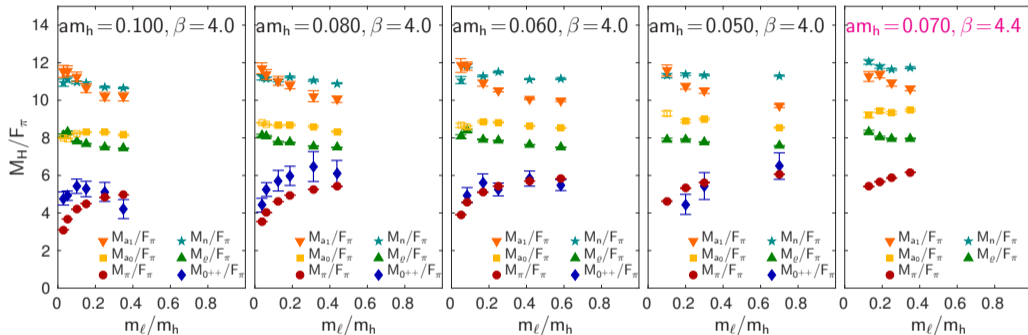

► Light flavors of mass \widehat{m}_ℓ and heavy flavors of mass \widehat{m}_h :

$$\begin{aligned} C_H(t; g, \widehat{m}_h, \widehat{m}_\ell, \mu) &\rightarrow b^{-2y_H} C_H(t/b; g^*, b^{y_m} \widehat{m}_h, b^{y_m} \widehat{m}_\ell, \mu) \\ &\equiv b^{-2y_H} C_H(t/b; g^*, b^{y_m} \widehat{m}_h, \widehat{m}_\ell / \widehat{m}_h, \mu) \end{aligned}$$

⇒ $aM_H \propto (\widehat{m})^{1/y_m} f_H(m_\ell/m_h)$ with $f_H(m_\ell/m_h)$ a universal function

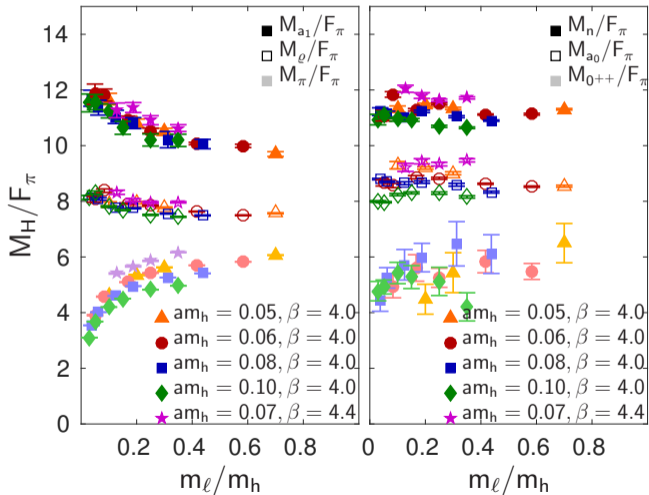

⇒ ratios depend only on m_ℓ/m_h

Light-light spectrum: ratios of M_H/F_π

- ▶ Pion, rho, a_0 , a_1 , nucleon, and 0^{++} scalar (statistical errors only)
- ▶ 0^{++} is light ($M_{0^{++}} < M_\rho$), it tracks the pion. Chiral limit?
- ▶ M_π/F_π bends down \Rightarrow indicates system is chirally broken
- ▶ Dimensionless ratios! No scale setting needed

Hyperscaling at work

- ▶ $M_n/F_\pi \approx 11$
- ▶ $M_\rho/F_\pi \approx 8$
- ▶ $M_{0^{++}}/F_\pi \approx 4 - 5$
(taking the chiral limit is difficult but 0^{++} well separated from the ρ)
- ▶ Statistical errors only
- ▶ “Scatter” indicates corrections to scaling
- ▶ Gauge coupling is irrelevant

The system is chirally broken

▶ All data points in a_\star units

▶ $a_\star F_\pi$ is finite

▶ Linearity in M_π^2 for small m_ℓ

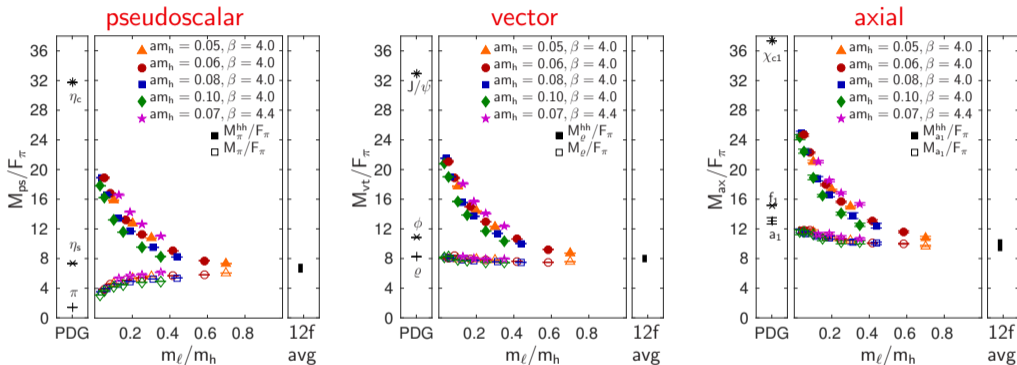

▶ QCD: $m_d/m_s = 4.7/96 \approx 0.05$

▶ $N_f = 4$ (QCD-like): ratio diverges

▶ $N_f = 12$: almost constant ratio

[Cheng et al. 2014]

Light-light and heavy-heavy spectrum

- ▶ 4+8 heavy-heavy spectrum is not QCD-like; QCD is not hyperscaling
- ▶ M^{hh}/F_π increases but F_π is finite in the chiral limit
- ▶ $M_\rho^{hh} \sim 3M_\rho \Rightarrow$ could be accessible at the LHC
- ▶ Data at $\beta = 4.0$ and 4.4 : **gauge coupling is irrelevant**

The challenge of computing the 0⁺⁺

- ▶ Same quantum numbers as the vacuum (large background)
- ▶ Fermionic states can mix with glueballs
 - Computing the glueball spectrum is a challenge on its own
- ▶ Connected and disconnected (only gluon-lines) contributions
 - For large t : disconnected part dominates
 - Stochastic determination of disconnected parts
 - Mass-split systems: light-light, heavy-light and heavy-heavy 0⁺⁺ can mix
 - ⇒ More expensive but noisier than connected meson spectrum
- ▶ Easier to compute in some BSM theories if 0⁺⁺ is “light”
 - $aM_{0^{++}} < 2aM_{\pi}$ i.e. not as difficult as in QCD

σ or $f_0(500)$ in QCD

- ▶ Caprini, Colangelo, Leutwyler: $M_\sigma = 441 \left(\begin{smallmatrix} +16 \\ -8 \end{smallmatrix} \right)$ MeV, $\Gamma_\sigma = 544 \left(\begin{smallmatrix} +18 \\ -25 \end{smallmatrix} \right)$ MeV (based on Roy equation) [PRL 96 (2006) 132001]
- ▶ Garcia-Martin et al. (dispersive analysis) confirms existence of σ and $f_0(980)$ [PRL 107 (2011) 072001]

▶ Hadron spectrum calculation

[Briceño et al., PRL 118 (2017) 0222002]

→ $\pi - \pi$ scattering phase shift calculation

→ Qualitatively different behavior

↪ $M_\pi = 391$ MeV: **bound state**,
 $M_\sigma = 758(4)$ MeV

↪ $M_\pi = 236$ MeV: **broad resonance**

0⁺⁺

[QCD] $M_\sigma = 400 - 550 \text{ MeV}$
 $> 2M_\pi = 276 \text{ MeV}$

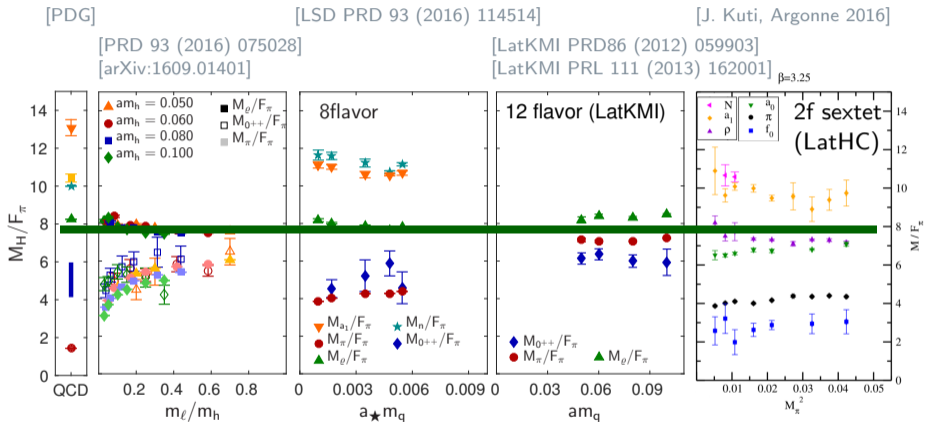

[8f] $aM_{0^{++}} \sim aM_\pi$
 Conformal? Chirally broken?

[2f sextet] $aM_{0^{++}} < aM_\pi$
 Is the theory conformal?

[4+8] $aM_{0^{++}} \gtrsim aM_\pi$
 Is the 0⁺⁺ “peeling off”?

[12f] $aM_{0^{++}} < aM_\pi$
 Theory is conformal

Magic 8

Concluding remarks

- ▶ Our model with four light and eight heavy flavors exhibits
 - a large separation of scales
 - walking gauge coupling (appendix)
 - $M_\pi \sim M_{0^{++}} < M_\rho$
 - **hyperscaling**: ratios depend only on m_ℓ/m_h
 - **predictive**: only scale to be set using e.g. F_π
 - **main results derived/shown for dimensionless ratios!**
- ▶ Heavy-heavy (and heavy-light) spectrum accessible but **not** QCD-like
- ▶ 0⁺⁺: challenging to compute, several models exhibit $M_{0^{++}} \sim M_\pi$

Outlook: four light and six heavy flavors

- closer to boundary of the conformal window; **larger anomalous dimension**
- theoretically clean, but expensive domain-wall fermions \Rightarrow test of fermion universality near IRFP

appendix

Fundamental composite 2HDM with 4 flavors [Ma and Cacciapaglia JHEP 03 (2016) 211]

- ▶ Global symmetry at low energies:

$$SU(4) \times SU(4) \text{ broken to } SU(4)_{\text{diag}}$$

- ▶ 15 pNGB transform under custodial symmetry

$$SU(2)_L \times SU(2)_R \quad \Rightarrow \quad \mathbf{15}_{SU(4)_{\text{diag}}} = (2, 2) + (2, 2) + (3, 1) + (1, 3) + (1, 1)$$

- One doublet plays the role of the Higgs doublet field
 - Other doublet and triplets are stable; could play role of dark matter
- ▶ Vecchi: “choose the right couplings to RH top” [Edinburgh talk]

$$\Rightarrow (2, 2) + \cancel{(2, 2)} + \cancel{(3, 1)} + \cancel{(1, 3)} + (1, 1) \rightsquigarrow \text{effectively } SU(4)/Sp(4)$$

On the lattice

▶ Setup

- ▶ SU(3) gauge group
- ▶ Fundamental adjoint gauge action with $\beta_a = -\beta/4$
[Cheng et al. arXiv:1311.1287][Cheng et al. PRD 90 (2014) 014509]
- ▶ nHYP smeared staggered Fermions [Hasenfratz et al. JHEP 05 (2007) 029]
- ▶ Most simulations/measurements performed with FUEL [J. Osborn]

▶ Goals

- ▶ Explore near conformal or conformal dynamics
- ▶ Compute the iso-singlet 0^{++}

▶ References

[JETP 120 (2015) 3, 423] [PoS Lattice2014 254] [CCP proceedings 2014] [PRD 93 (2016) 075028] [arXiv:1609.01401]
(a longer, detailed paper is in preparation)

QCD:

- chirally broken, simulate at finite $\beta = 6/g^2$
- correlation functions show (at large distance) exponential behavior
- for $\beta \rightarrow \infty$, $aF_\pi \rightarrow 0$; ratios will approach well defined limits
- β is relevant; take continuum limit by $\beta \rightarrow \infty$

4+8:

- four flavors are massless ($m_\ell = 0$), eight are massive with mass m_h
- correlation functions show (at large distance) exponential behavior
- for m_h sufficiently small, β is irrelevant
- m_h is relevant; take continuum limit by $m_h \rightarrow 0$ for fixed m_ℓ/m_h
- ratios will be independent of m_h and β (hyperscaling)

$N_f = 12$:

- (it appears) theory is conformal and choose $\beta > \beta_{cr}$
- correlation functions show (at large distance) power law behavior
- rescaling lengths results in the same long range behavior for any two β values
- under RG transformations theory runs to an IRFP
- β is irrelevant, masses or amplitudes show hyperscaling

Performed simulations ($\beta = 4.0$)

running coupling

Running coupling form gradient flow

- ▶ Gradient flow defines the renormalized coupling

[Narayanan and Neuberger JHEP 03 (2006) 064], [Lüscher JHEP 08 (2010) 071]

$$g_{GF}^2(\mu = 1/\sqrt{8t}) = t^2 \langle E(t) \rangle / \mathcal{N}$$

t : flow time; $E(t)$ energy density

- ▶ g_{GF}^2 is used for scale setting

$$g_{GF}^2(t = t_0) = 0.3/\mathcal{N} \quad (\text{"}t_0\text{-scale"})$$

- ▶ Can determine renormalized running coupling on large enough volumes and large enough flow times in the continuum limit

Running coupling form gradient flow: 4+8 flavors

- ▶ Extrapolated to $m_\ell = 0$
- ▶ $N_f = 4$ shows fast running
- ▶ “Shoulder” increases for smaller m_h
 \Rightarrow walking
- ▶ Walking range is tuned as function of m_h
- ▶ Data with error bars!

The 0^{++}

Calculating the disconnected spectrum (0^{++} scalar)

Numerical measurement on the lattice

- ▶ 6 U(1) sources with dilution on each time slice, color and even/odd spatially
- ▶ Variance reduced $\langle \bar{\psi}\psi \rangle$

Analysis strategy

- ▶ Correlated fit to both parity states (staggered)
- ▶ **Vacuum subtraction** introduces very large uncertainties
- ▶ Advantageous to fit additional constant

$$C(t) = c_{0^{++}} \cosh \left(M_{0^{++}} \left(\frac{N_T}{2} - t \right) \right) + c_{\pi_{sc}} (-1)^t \cosh \left(M_{\pi_{sc}} \left(\frac{N_T}{2} - t \right) \right) + \nu$$

- ▶ Equivalent to fitting the finite difference: $C(t+1) - C(t)$

Comparison of $D_{\ell\ell}$ and $D_{\ell\ell} - C_{\ell\ell}$

- ▶ For $t \rightarrow \infty$: $D_{\ell\ell}$ and $D_{\ell\ell} - C_{\ell\ell}$ should agree (up to mixing effects)
- ▶ Compare fits with different t_{\min} and $t_{\max} = N_T/2$
- ▶ Compare results for two volumes
- ⇒ Consistent results!
