

Measurements of the W boson mass with the D0 detector

Thursday, 15 August 2013 11:30 (20 minutes)

We present a measurement of the W boson mass using data corresponding to an integrated luminosity of 4.3 fb⁻¹ collected with the D0 detector during Run 2 at the Fermilab Tevatron ppbar collider. With a sample of 1,677,394 W → e ν candidate events, we measure $M_W = 80.367 \pm 0.026$ GeV. This result is combined with an earlier D0 result determined using an independent Run 2 data sample, corresponding to 1 fb⁻¹ of integrated luminosity, to yield $M_W = 80.375 \pm 0.023$ GeV.
