Cross section measurements of kinematically reconstructed weak bosons in unpolarized p+p collisions at STAR

Wednesday, 25 March 2020 09:50 (20 minutes)

We present cross sections for the weak bosons measured by the STAR experiment at RHIC in unpolarized proton-proton collisions at $\sqrt{s} = 500(510)$ GeV. The results combine data from run 2011, 2012, and 2013, corresponding to an integrated luminosity of $350\text{-}pb^{-1}$. The differential Z^0 cross section measured as a function of the boson's p_T , provides important constraints on the energy dependence of intrinsic transverse momentum effects of partons inside the proton. The W^+/W^- cross-section ratio as function of the boson's rapidity, is sensitive to the non-perturbative \bar{d}/\bar{u} distribution. The probed x range ($0.1 < x < 0.3$) covered by our data naturally complements the phase space accessed at the LHC, providing critical input to global fits.
