## First measurement of diffraction in pPb and pp collisions with CMS and Search for elliptic azimuthal anisotropies in $\gamma p$ interactions within ultra-peripheral pPb collisions at $sqrts_{NN}$ = 8.16 TeV

We present a first measurement of two-particle angular correlations for charged hadrons emitted from photonproton,  $\gamma p$ , interactions over a wide range of pseudorapidity and full azimuth. The  $\gamma p$  events were produced within ultra-peripheral pPb collisions at  $\sqrt{s_{NN}} = 8.16$  TeV and were selected by requiring a large rapidity gap in the lead-going direction and no neutron emission from the lead nucleus. The results are compared to a sample of minimum-bias pPb events with same multiplicity. The observed azimuthal correlations at large relative pseudorapidity are used to extract the first, second and third-order two-particle anisotropy harmonics, V1D, V2D, and V3D as a function of track multiplicity and transverse momentum pT. For both the photon-p and minimum-bias pPb samples V1D is negative, V2D is positive and V3D is negative but consistent with zero. The single particle second-order harmonic, v2 (pT) is larger for photon-p events than for minimum-bias pPb collisions of the same multiplicity.
