Leading-order hadronic contribution to $g_\mu - 2$ from $N_f = 2 + 1$ simulations down to the physical pion mass

Friday, 27 June 2014 14:35 (20 minutes)

For the Budapest-Marseille-Wuppertal collaboration.

We present preliminary lattice QCD results for the leading-order hadronic contribution to the muon anomalous magnetic moment. Computations are based on $2+1$ flavour simulations with HEX-smearred clover fermions and pion masses down to its physical value. Besides the traditional approach, several methods implementing derivatives of the hadronic vacuum polarization are investigated and compared.
