## Long-distance contributions to flavour-changing processes

## Chris Sachrajda

School of Physics and Astronomy<br>University of Southampton<br>Southampton SO17 1BJ<br>UK<br>(RBC-UKQCD Collaboration)<br>\section*{Lattice 2014<br><br>22-28 June 2014}

- Our satisfaction at the discovery of the Higgs Boson is (temporarily?) tempered by the absence of a discovery of new physics at the LHC.
- Precision Flavour physics is a key tool, complementary to the LHC, in exploring the limits of the Standard Model of Particle Physics and in searches for new physics.
- If the LHC experiments discover new elementary particles BSM, then precision flavour physics will be necessary to understand the underlying framework.
- The discovery potential of precision flavour physics should also not be underestimated. (In principle, the reach is about two-orders of magnitude deeper than the LHC!)
- Precision flavour physics requires control of hadronic effects for which lattice QCD simulations are essential.
- It is surprising that no unambiguous inconsistencies have arisen up to now.
- At this conference we have seen the continued, hugely impressive, improvement in precision for a wide range of quantities.
- As a community we still have work to do to convince some of our HEP colleagues of the validity of the results:

Question at EPS2013: Can we trust the lattice?
CTS@EPS 1993- $\hat{B}_{K}=0.8(2)$,
CTS@EPS 2013- $\hat{B}_{K}=0.766(10)$.

- Standard quantities include the spectrum and matrix elements of the form $\langle 0| O|h\rangle$ and $\left\langle h_{2}\right| O\left|h_{1}\right\rangle$, where the $O$ are local composite operators and $h, h_{1}, h_{2}$ are hadrons.
- We are seeing the range of $O$ and $h, h_{1}, h_{2}$ extended.
- We are seeing the extension to two-hadron states (including $K \rightarrow \pi \pi$ ).

> see e.g. talks by R.Briceno \& T.Yamazaki.

- In this talk I will discuss 3 topics in which the matrix elements are of non-local operators involving long-distance effects:
$11 \Delta m_{K}=m_{K_{L}}-m_{K_{S}}$.

& \Delta m_{K} \equiv m_{K_{L}}-m_{K_{S}}=3.483(6) \times 10^{-12} \mathrm{MeV}
\end{aligned}
$$

－Historically led to the prediction of the energy scale of the charm quark．
Mohapatra，Rao \＆Marshak（1968）；GIM（1970）；Gaillard \＆Lee（1974）
－Tiny quantity $\Rightarrow$ places strong constraints on BSM Physics．
－Within the standard model，$\Delta m_{K}$ arises from $K^{0}-\bar{K}^{0}$ mixing at second order in the weak interactions：

$$
\Delta M_{K}=2 \mathscr{P} \sum_{\alpha} \frac{\left\langle\bar{K}^{0}\right| H_{W}|\alpha\rangle\langle\alpha| H_{W}\left|K^{0}\right\rangle}{m_{K}-E_{\alpha}}
$$

where the sum over $|\alpha\rangle$ includes an energy－momentum integral．

## The fiducial volume

－How do you prepare the states $h_{1,2}$ in the generic integrated correlation function：

$$
\int d^{4} x \int d^{4} y\left\langle h_{2}\right| T\left\{O_{1}(x) O_{2}(y)\right\}\left|h_{1}\right\rangle,
$$

when the time of the operators is integrated？
－The practical solution is to integrate over a large subinterval in time $t_{A} \leq t_{x, y} \leq t_{B}$ ， but to create $h_{1}$ and to annihilate $h_{2}$ well outside of this region．
－This is the natural modification of standard field theory for which the asymptotic states are prepared at $t \rightarrow \pm \infty$ and then the operators are integrated over all time．
－This approach has been successfully implemented in the $\Delta M_{K}$ project as explained below．
$\Delta m_{K}^{\mathrm{FV}}$

- $\Delta m_{K}$ is given by

$$
\Delta m_{K} \equiv m_{K_{L}}-m_{K_{S}}=2 \mathscr{P} \sum_{\alpha} \frac{\left\langle\bar{K}^{0}\right| \mathscr{H}_{W}|\alpha\rangle\langle\alpha| \mathscr{H}_{W}\left|K^{0}\right\rangle}{m_{K}-E_{\alpha}}=3.483(6) \times 10^{-12} \mathrm{MeV}
$$

- The above correlation function gives $\left(T=t_{B}-t_{A}+1\right)$

$$
\begin{aligned}
C_{4}\left(t_{A}, t_{B} ; t_{i}, t_{f}\right)=\left|Z_{K}\right|^{2} e^{-m_{K}\left(t_{f}-t_{i}\right)} & \sum_{n} \frac{\left\langle\bar{K}^{0}\right| \mathscr{H}_{W}|n\rangle\langle n| \mathscr{H}_{W}\left|K^{0}\right\rangle}{\left(m_{K}-E_{n}\right)^{2}} \times \\
& \left\{e^{\left(M_{K}-E_{n}\right) T}-\left(m_{K}-E_{n}\right) T-1\right\}
\end{aligned}
$$

- From the coefficient of $T$ we can therefore obtain

$$
\Delta m_{K}^{\mathrm{FV}} \equiv 2 \sum_{n} \frac{\left\langle\bar{K}^{0}\right| \mathscr{H}_{W}|n\rangle\langle n| \mathscr{H}_{W}\left|K^{0}\right\rangle}{\left(m_{K}-E_{n}\right)} .
$$

## Exponentially growing exponentials

$$
\begin{gathered}
C_{4}\left(t_{A}, t_{B} ; t_{i}, t_{f}\right)=\left|Z_{K}\right|^{2} e^{-m_{K}\left(t_{f}-t_{i}\right)} \sum_{n} \frac{\left\langle\bar{K}^{0}\right| \mathscr{H}_{W}|n\rangle\langle n| \mathscr{H}_{W}\left|K^{0}\right\rangle}{\left(m_{K}-E_{n}\right)^{2}} \times \\
\left\{e^{\left(M_{K}-E_{n}\right) T}-\left(m_{K}-E_{n}\right) T-1\right\} .
\end{gathered}
$$

－The presence of terms which（potentially）grow exponentially in $T$ is a generic feature of calculations of matrix elements of bilocal operators．
－There can be $\pi^{0}$ or vacuum intermediate states．
－The corresponding growing exponentials can be eliminated by adding $c_{S}(\bar{s} d)+c_{P}\left(\bar{s} \gamma^{5} d\right)$ to $H_{W}$ ，with coefficients $c_{S}$ and $c_{P}$ chosen such that $\left\langle\pi^{0}\right| H_{W}|K\rangle$ and $\langle 0| H_{W}|K\rangle$ are both zero．
－There are two－pion contributions with $E_{\pi \pi}<m_{K}$ ．（Number of such states grows as $L \rightarrow \infty$ ，as in the calculation of $K \rightarrow \pi \pi$ decay amplitudes．）

- For s-wave two-pion states, Lüscher's quantization condition is $h(E, L) \pi \equiv \phi(q)+\delta(k)=n \pi$, where $q=k L / 2 \pi, \phi$ is a kinematical function and $\delta$ is the physical s-wave $\pi \pi$ phase shift for the appropriate isospin state.
M. Lüscher, NPB 354 (1991) 531
- The relation between the physical $K \rightarrow \pi \pi$ amplitude $A$ and the finite-volume matrix element $M$
L.Lellouch and M.Lüscher, hep-lat/0003023

$$
|A|^{2}=8 \pi V^{2}\left(\frac{m_{K}}{k}\right)^{3}\left\{k \delta^{\prime}(k)+q \phi^{\prime}(q)\right\}|M|^{2}
$$

- In addition to simple factors related to the normalization of states, the LL factor accounts for the non-exponential FV corrections.
- The evaluation of the non-exponential finite-volume corrections in the calculation of $\Delta m_{K}$ requires an extension of the LL formalism.
1 At Lattice 2010, N.Christ, using degenerate perturbation theory, presented the result for the case when the volume is such that there is a state $n_{0}$ with $E_{n_{0}}=m_{K}$.
N.H.Christ, arXiv:1012.6034

2 At Lattice 2013, I presented the result for the general (s-wave) rescattering case.
N.H.Christ, G.Martinelli \& CTS, arXiv:1401.1362 N.H.Christ, X.Feng, G.Martinelli \& CTS, in preparation

- The general formula can be written:
N.H.Christ, G.Martinelli \& CTS, arXiv:1401.1362 N.H.Christ, X.Feng, G.Martinelli \& CTS, in preparation

$$
\Delta m_{K}=\Delta m_{K}^{\mathrm{FV}}-2 \pi_{V}\left\langle\bar{K}^{0}\right| H\left|n_{0}\right\rangle_{V V}\left\langle n_{0}\right| H\left|K^{0}\right\rangle_{V}\left[\cot \pi h \frac{d h}{d E}\right]_{m_{K}}
$$

where $h(E, L) \pi \equiv \phi(q)+\delta(k)$.

- This formula reproduces the result for the special case when the volume is such that there is a two-pion state with energy $=m_{K}$.
N.H.Christ, arXiv:1012.6034
- Increasing the volumes keeping $h=n / 2$ and thus avoiding the power corrections is an intriguing possibility.

## Ultraviolet Divergences

- The $\Delta S=1$ effective Weak Hamiltonian takes the form:

$$
H_{W}=\frac{G_{F}}{\sqrt{2}} \sum_{q, q^{\prime}=u, c} V_{q d} V_{q^{\prime} s}^{*}\left(C_{1} Q_{1}^{q q^{\prime}}+C_{2} Q_{2}^{q q^{\prime}}\right)
$$

where the $\left\{Q_{i}^{q q \prime}\right\}_{i=1,2}$ are current-current operators, defined as:

$$
\begin{aligned}
& Q_{1}^{q q^{\prime}}=\left(\bar{s}_{i} \gamma^{\mu}\left(1-\gamma^{5}\right) d_{i}\right)\left(\bar{q}_{j} \gamma^{\mu}\left(1-\gamma^{5}\right) q_{j}^{\prime}\right) \\
& Q_{2}^{q q^{\prime}}=\left(\bar{s}_{i} \gamma^{\mu}\left(1-\gamma^{5}\right) d_{j}\right)\left(\bar{q}_{j} \gamma^{\mu}\left(1-\gamma^{5}\right) q_{i}^{\prime}\right)
\end{aligned}
$$

- As the two $H_{W}$ approach each other, we have the potential of new ultraviolet divergences.
- Taking the $u$-quark component of the operators $\Rightarrow$ a quadratic divergence.

- GIM mechanism \& $V-A$ nature of the currents $\Rightarrow$ elimination of both quadratic and logarithmic divergences.
- Short distance contributions come from distances of $O\left(1 / m_{c}\right)$.
- There are four types of diagram to be evaluated:

- In our first exploratory study on $16^{3}$ ensembles with $m_{\pi}=420 \mathrm{MeV}$, ( $1 / a=1.73 \mathrm{GeV}$ ) we only evaluated Type 1 and Type 2 graphs.
N.Christ, T.Izubuchi, CTS, A.Soni \& J.Yu, arXiv:1212.5931
- In our more recent study, we evaluated all the diagrams.

## Z.Bai, N.H.Christ, T.Izubuchi, CTS, A.Soni \& J.Yu, arXiv:1406.0916

- We have performed a full calculation of $\Delta m_{K}$, using 800 gauge configurations (separated by 10 time units) on a $24^{3} \times 64 \times 16$ lattice, with DWF and the Iwasaki gauge action, $m_{\pi}=330 \mathrm{MeV}, m_{K}=575 \mathrm{MeV}, m_{c}^{\overline{\mathrm{MS}}}(2 \mathrm{GeV})=949 \mathrm{MeV}$, $1 / a=1.729(28) \mathrm{GeV}$ and $a m_{\mathrm{res}}=0.00308(4)$.

For details of the ensembles see arXiv:0804.0473 and 1011.0892

- At these unphysical parameters we find

$$
\Delta m_{K}=3.19(41)(96) \times 10^{-12} \mathrm{MeV}
$$

to be compared to the physical value $3.483(6) \times 10^{-12} \mathrm{MeV}$.

- Agreement with physical value may well be fortuitous, but it is nevertheless reassuring to obtain results of the correct order.
- Systematic error dominated by discretization effects related to the charm quark mass, which we estimate at $30 \%$.
- Here $m_{K}<2 m_{\pi}$ and so we do not have exponentially growing two-pion terms.

## Complete calculation of $\Delta m_{K}$ (cont.)

Type 1

Type 3

$$
\text { Type } 2
$$

Type 4

- Coulomb-gauge fixed wall sources used for the kaons.
- Point source propagators calculated for each of the 64 time slices (Types 1\&2).
- Random-source propagators on each time slice (Types 3\&4).

## Slopes

## Violation of the OZI rule

Type 1

Type 3

Type 2

Type 4

- One possible surprise(?) from this calculation is the large size of the disconnected diagrams of type 4.

| Diagrams | $Q_{1} \cdot Q_{1}$ | $Q_{1} \cdot Q_{2}$ | $Q_{2} \cdot Q_{2}$ | $\Delta M_{K}$ |
| :---: | :---: | :---: | :---: | :---: |
| Type 1,2 | $1.479(79)$ | $1.567(36)$ | $3.677(52)$ | $6.723(90)$ |
| All | $0.68(10)$ | $-0.18(18)$ | $2.69(19)$ | $3.19(41)$ |

- Type 3 contributions are small.
- At this conference Ziyuan Bai presented preliminary results from the RBC-UKQCD collaboration study on the $32^{3} \times 64$ DWF\&DSDR coarse lattice which had been used in the first computation of $K \rightarrow(\pi \pi)_{I=2}$ decay amplitudes.

| $m_{\pi}$ | $m_{K}$ | $m_{c}$ | $a^{-1}$ | $L$ | no. of configs. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 171 MeV | 492 MeV | $592 / 750 \mathrm{MeV}$ | 1.37 GeV | 4.6 fm | 212 |

- $m_{K}>2 m_{\pi} \Rightarrow$ allows us to study the effect of the two-pion intermediate state.
- We use the freedom to perform chiral rotations, to transform

$$
H_{W} \rightarrow H_{W}^{\prime}=H_{W}+c_{S}(\bar{s} d)+c_{P}\left(\bar{s} \gamma^{5} d\right)
$$

with $c_{S}$ and $c_{P}$ chosen so that

$$
\langle 0| H_{W}^{\prime}|K\rangle=0 \quad \text { and } \quad\langle\eta| H_{W}^{\prime}|K\rangle=0
$$

- Even though $m_{\eta}>m_{K}$, we find that the large errors associated with the $\eta \Rightarrow$ it is difficult to control the exponential suppression. We therefore find that it is more effective to eliminate the $\eta$ (rather than the pion).

## Preliminary results

| $m_{c}$ | $\Delta m_{K}$ |
| :---: | :---: |
| 750 MeV | $(4.6 \pm 1.3) \times 10^{-12} \mathrm{MeV}$ |
| 592 MeV | $(3.8 \pm 1.7) \times 10^{-12} \mathrm{MeV}$ |

- Only statistical errors are shown.
- The contributions from $\pi \pi$ intermediate states is small $\left(\Delta m_{K}(\pi \pi)_{I=0}=-0.133(99) \times 10^{-12} \mathrm{MeV}, \Delta m_{K}(\pi \pi)_{I=2}=-6.54(25) \times 10^{-16} \mathrm{MeV}\right)$.
- For $I=0$ the FV effects are $O(20 \%)$ of the $4 \%$ contribution (i.e. $\leq 1 \%$ ).
- Very promising indeed and in near-future calculations we will perform computations at physical kinematics and also on ensembles with unquenched charm quarks.
- For prospects for the calculation of $\varepsilon_{K}$ see:
N.H.Christ, T.Izubuchi, CTS, A.Soni and J.Yu, arXiv:1402.2577, Z.Bai, N.H.Christ, T.Izubuchi, CTS, A.Soni and J.Yu, arXiv:1406.0916.

Some comments from F.Mescia, C.Smith, S.Trine hep-ph/0606081:

- Rare kaon decays which are dominated by short-distance FCNC processes, $K \rightarrow \pi \nu \bar{v}$ in particular, provide a potentially valuable window on new physics at high-energy scales.
- The decays $K_{L} \rightarrow \pi^{0} e^{+} e^{-}$and $K_{L} \rightarrow \pi^{0} \mu^{+} \mu^{-}$are also considered promising because the long-distance effects are reasonably under control using ChPT.
- They are sensitive to different combinations of short-distance FCNC effects and hence in principle provide additional discrimination to the neutrino modes.
- A challenge for the lattice community is therefore either to calculate the long-distance effects reliably or at least to determine the Low Energy Constants of ChPT.
- We, N.Christ, X.Feng, A.Portelli, CTS and RBC-UKQCD, are attempting to meet this challenge.

$$
K_{L} \rightarrow \pi^{0} \ell^{+} \ell^{-}
$$

There are three main contributions to the amplitude：
1 Short distance contributions：

$$
H_{\text {eff }}=-\frac{G_{F} \alpha}{\sqrt{2}} V_{t s}^{*} V_{t d}\left\{y_{7 V}\left(\bar{s} \gamma_{\mu} d\right)\left(\bar{\ell} \gamma^{\mu} \ell\right)+y_{7 A}\left(\bar{s} \gamma_{\mu} d\right)\left(\overline{\bar{\gamma}} \gamma^{\mu} \gamma_{5} \ell\right)\right\}+\text { h.c. }
$$

－Direct CP－violating contribution．
－In BSM theories other effective interactions are possible．
2 Long－distance indirect CP－violating contribution

$$
A_{I C P V}\left(K_{L} \rightarrow \pi^{0} \ell^{+} \ell^{-}\right)=\varepsilon A\left(K_{1} \rightarrow \pi^{0} \ell^{+} \ell^{-}\right) .
$$

13 The two－photon CP－conserving contribution $K_{L} \rightarrow \pi^{0}\left(\gamma^{*} \gamma^{*} \rightarrow \ell^{+} \ell^{-}\right)$．

$$
K_{L} \rightarrow \pi^{0} \ell^{+} \ell^{-} \text {cont. }
$$

- The current phenomenological status for the SM predictions is nicely summarised by:
V.Cirigliano et al., arXiv1107.6001

$$
\begin{aligned}
\operatorname{Br}\left(K_{L} \rightarrow \pi^{0} e^{+} e^{-}\right)_{\mathrm{CPV}} & =10^{-12} \times\left\{15.7\left|a_{S}\right|^{2} \pm 6.2\left|a_{S}\right|\left(\frac{\operatorname{Im} \lambda_{t}}{10^{-4}}\right)+2.4\left(\frac{\operatorname{Im} \lambda_{t}}{10^{-4}}\right)^{2}\right\} \\
\operatorname{Br}\left(K_{L} \rightarrow \pi^{0} \mu^{+} \mu^{-}\right)_{\mathrm{CPV}} & =10^{-12} \times\left\{3.7\left|a_{S}\right|^{2} \pm 1.6\left|a_{S}\right|\left(\frac{\operatorname{Im} \lambda_{t}}{10^{-4}}\right)+1.0\left(\frac{\operatorname{Im} \lambda_{t}}{10^{-4}}\right)^{2}\right\}
\end{aligned}
$$

$-\lambda_{t}=V_{t d} V_{t s}^{*}$ and $\operatorname{Im} \lambda_{t} \simeq 1.35 \times 10^{-4}$.

- $\left|a_{S}\right|$, the amplitude for $K_{S} \rightarrow \pi^{0} \ell^{+} \ell^{-}$at $q^{2}=0$ as defined below, is expected to be $O(1)$ but the sign of $a_{S}$ is unknown. $\left|a_{S}\right|=1.06_{-0.21}^{+0.26}$.
- For $\ell=e$ the two-photon contribution is negligible.
- Taking the positive sign (?) the prediction is

$$
\begin{aligned}
\operatorname{Br}\left(K_{L} \rightarrow \pi^{0} e^{+} e^{-}\right)_{\mathrm{CPV}} & =(3.1 \pm 0.9) \times 10^{-11} \\
\operatorname{Br}\left(K_{L} \rightarrow \pi^{0} \mu^{+} \mu^{-}\right)_{\mathrm{CPV}} & =(1.4 \pm 0.5) \times 10^{-11} \\
\operatorname{Br}\left(K_{L} \rightarrow \pi^{0} \mu^{+} \mu^{-}\right)_{\mathrm{CPC}} & =(5.2 \pm 1.6) \times 10^{-12}
\end{aligned}
$$

- The current experimental limits (KTeV) are:

$$
\operatorname{Br}\left(K_{L} \rightarrow \pi^{0} e^{+} e^{-}\right)<2.8 \times 10^{-10} \quad \text { and } \quad \operatorname{Br}\left(K_{L} \rightarrow \pi^{0} \mu^{+} \mu^{-}\right)<3.8 \times 10^{-10}
$$

- We now turn to the CPC decays $K_{S} \rightarrow \pi^{0} \ell^{+} \ell^{-}$and $K^{+} \rightarrow \pi^{+} \ell^{+} \ell^{-}$and consider

$$
T_{i}^{\mu}=\int d^{4} x e^{-i q \cdot x}\langle\pi(p)| \mathrm{T}\left\{J_{\mathrm{em}}^{\mu}(x) Q_{i}(0)\right\}|K(k)\rangle
$$

where $Q_{i}$ is an operator from the effective Hamiltonian.

- EM gauge invariance implies that

$$
T_{i}^{\mu}=\frac{\omega_{i}\left(q^{2}\right)}{(4 \pi)^{2}}\left\{q^{2}(p+k)^{\mu}-\left(m_{K}^{2}-m_{\pi}^{2}\right) q^{\mu}\right\}
$$

- Within ChPT the Low energy constants $a_{+}$and $a_{S}$ are defined by

$$
a=\frac{1}{\sqrt{2}} V_{u s}^{*} V_{u d}\left\{C_{1} \omega_{1}(0)+C_{2} \omega_{2}(0)+\frac{2 N}{\sin ^{2} \theta_{W}} f_{+}(0) C_{7 V}\right\}
$$

where $Q_{1,2}$ are the two current-current GIM subtracted operators and the $C_{i}$ are the Wilson coefficients. ( $C_{7 V}$ is proportional to $y_{7 V}$ above).
G.D'Ambrosio, G.Ecker, G.Isidori and J.Portoles, hep-ph/9808289

- Phenomenological values: $a_{+}=-0.578 \pm 0.016$ and $\left|a_{S}\right|=1.06_{-0.21}^{+0.26}$.

Can we do better in lattice simulations?

## Minkowski and Euclidean Correlation Functions

- The generic non-local matrix elements which we wish to evaluate is

$$
\begin{aligned}
X & \equiv \int_{-\infty}^{\infty} d t_{x} d^{3} x\langle\pi(p)| \mathrm{T}[J(0) H(x)]|K\rangle \\
& =i \sum_{n} \frac{\langle\pi(p)| J(0)|n\rangle\langle n| H(0)|K\rangle}{m_{K}-E_{n}+i \varepsilon}-i \sum_{n_{s}} \frac{\langle\pi(p)| H(0)\left|n_{s}\right\rangle\left\langle n_{s}\right| J(0)|K\rangle}{E_{n_{s}}-E_{\pi}+i \varepsilon}
\end{aligned}
$$

- $\{|n\rangle\}$ and $\left\{\left|n_{s}\right\rangle\right\}$ represent complete sets of non-strange and strange sets.
- In Euclidean space we envisage calculating correlation functions of the form

$$
C \equiv \int_{-T_{a}}^{T_{b}} d t_{x}\left\langle\phi_{\pi}\left(\vec{p}, t_{\pi}\right) \mathrm{T}\left[J(0) H\left(t_{x}\right)\right] \phi_{K}^{\dagger}\left(t_{K}\right)\right\rangle \equiv \sqrt{Z_{K}} \frac{e^{-E_{K}\left|t_{K}\right|}}{2 m_{K}} X_{E} \sqrt{Z_{\pi}} \frac{e^{-E_{\pi} t_{\pi}}}{2 E_{\pi}}
$$

where

$$
\begin{aligned}
& X_{E_{-}}=-\sum_{n} \frac{\langle\pi(p)| J(0)|n\rangle\langle n| H(0)|K\rangle}{E_{K}-E_{n}}\left(1-e^{\left(E_{K}-E_{n}\right) T_{a}}\right) \quad \text { and } \\
& X_{E_{+}}=\sum_{n_{s}} \frac{\langle\pi(p)| H(0)\left|n_{s}\right\rangle\left\langle n_{s}\right| J(0)|K\rangle}{E_{n_{s}}-E_{\pi}}\left(1-e^{-\left(E_{n_{s}}-E_{\pi}\right) T_{b}}\right)
\end{aligned}
$$

- We can remove the single pion intermediate state.
- Which intermediate states contribute?
- Are there any states below $M_{K}$ ?
- We can control $q^{2}$ and stay below the two-pion threshold.

- Do the symmetries protect us completely from two-pion intermediate states at low $q^{2}$ ?
- Are the contributions from three-pion intermediate states negligible?
- Answers to the above questions will affect what the finite-volume corrections are?
- The ChPT-based phemomenology community neglect such possibilities as they are higher order in the chiral expansion.

## All to be investigated further!

- It looks as though the FV corrections are much simpler than for $\Delta M_{K}$ and may be exponentially small?

$$
T_{i}^{\mu}=\int d^{4} x e^{-i q \cdot x}\langle\pi(p)| \mathrm{T}\left\{J^{\mu}(x) Q_{i}(0)\right\}|K(k)\rangle,
$$

- Each of the two local $Q_{i}$ operators can be normalized in the standard way and for $J$ we imagine taking the conserved vector current.
- We must treat additional divergences as $x \rightarrow 0$.

- Quadratic divergence is absent by gauge invariance $\Rightarrow$ Logarithmic divergence.
- Checked explicitly for Wilson and Clover at one-loop order.
G.Isidori, G.Martinelli and P.Turchetti, hep-lat/0506026
- Absence of power divergences does not require GIM.
- Logarithmic divergence cancelled by GIM.
- For DWF the same applies for the axial current.
- To be investigated further!
- For example for $K^{+}$decays we need to evaluate the diagrams obtained by inserting the current at all possible locations in the three point function (and adding the disconnected diagrams):

W

C

- $W=$ Wing, $C=$ Connected, $S=$ Saucer, $E=E y e$.
- For $K_{S}$ decays there is an additional topology with a gluonic intermediate state.
- For the first exploratory study, we have only considered the $W$ and $C$ diagrams.

## Exploratory numerical study

- The numerical study is performed on the $24^{3} \times 64$ DWF+lwasaki RBC-UKQCD ensembles with $a m_{l}=0.01\left(m_{\pi} \simeq 420 \mathrm{MeV}\right), a m_{s}=0.04, a^{-1} \simeq 1.73 \mathrm{fm}$.
- 127 configurations were used with $\vec{k}=(1,0,0) \frac{2 \pi}{L}$ and $\vec{p}=0$.
- The calculation is performed using the conserved vector current (5-dimensional), $J^{0}$.

## Unintegrated 4-point Correlation Function

- $t_{K}=0, t_{\pi}=28$ and $t_{J}=14$. $x$-coordinate is $t_{H}$.
- Blue band - Result from 2\&3 point-functions assuming ground state contributions between $t_{J}$ and $t_{H}$. (No fit here.)

## Integrated 4－point Correlation Function

－In this plot $T_{b}=9$ ，so that the integral is from the $x$－coordinate to 23 ．
－It appears that the subtraction of the exponentially growing term can be performed and a constant result obtained．
－These are just the beginnings－much work still to be done．

N.Carrasco, V.Lubicz, G.Martinelli, CTS, F.Sanfillipo, N.Tantalo, C.Tarantino, M.Testa

(in preparation)

- For a review of electromagnetic mass-splittings see the talk by A.Portelli at this conference.
- The evaluation of (some) weak matrix elements are now being quoted with $O(1 \%)$ precision e.g.

FLAG Collaboration, arXiv:1310.8555

| (results given in MeV) |  |  |  |  |  |

- We therefore need to start considering electromagnetic (and other isospin breaking) effects if we are to use these results to extract CKM matrix elements at a similar precision.
- For illustration, I consider $f_{\pi}$ but the discussion is general. I do not use ChPT. For a ChPT based discussion of $f_{\pi}$, see J.Gasser \& G.R.S.Zarnauskas, arXiv:1008.3479
- At $O\left(\alpha^{0}\right)$

$$
\Gamma\left(\pi^{+} \rightarrow \ell^{+} v_{\ell}\right)=\frac{G_{F}^{2}\left|V_{u d}\right|^{2} f_{\pi}^{2}}{8 \pi} m_{\pi} m_{\ell}^{2}\left(1-\frac{m_{\ell}^{2}}{m_{\pi}^{2}}\right)^{2}
$$

- At $O(\alpha)$ infrared divergences are present and we have to consider

$$
\begin{aligned}
\Gamma\left(\pi^{+} \rightarrow \ell^{+} v_{\ell}(\gamma)\right) & =\Gamma\left(\pi^{+} \rightarrow \ell^{+} v_{\ell}\right)+\Gamma\left(\pi^{+} \rightarrow \ell^{+} v_{\ell} \gamma\right) \\
& \equiv \Gamma_{0}+\Gamma_{1},
\end{aligned}
$$

where the suffix denotes the number of photons in the final state.

- Each of the two terms on the rhs is infrared divergent, the divergences cancel in the sum.
- The cancelation of infrared divergences between contributions with virtual and real photons is an old and well understood issue.
F.Bloch and A.Nordsieck, PR $\underline{52}$ (1937) 54
- The question for our community is how best to combine this understanding with lattice calculations of non-perturbative hadronic effects.
- This is a generic problem if em corrections are to be included in the evaluation of a decay process.
- At this stage we do not propose to compute $\Gamma_{1}$ nonperturbatively. Rather we consider only photons which are sufficiently soft for the point-like (pt) approximation to be valid.
- A cut-off $\Delta$ of $O(10 \mathrm{MeV})$ appears to be appropriate both experimentally and theoretically.
- (In the future, as techniques and resources improve, it may be better to compute $\Gamma_{1}$ nonperturbatively over a larger range of photon energies.)
- We now write

$$
\Gamma_{0}+\Gamma_{1}(\Delta)=\lim _{V \rightarrow \infty}\left(\Gamma_{0}-\Gamma_{0}^{\mathrm{pt}}\right)+\lim _{V \rightarrow \infty}\left(\Gamma_{0}^{\mathrm{pt}}+\Gamma_{1}(\Delta)\right) .
$$

- The second term on the rhs can be calculated in perturbation theory. It is infrared convergent, but does contain a term proportional to $\log \Delta$.
- The first term is also free of infrared divergences.
- $\Gamma_{0}$ is calculated nonperturbatively and $\Gamma_{0}^{\mathrm{pt}}$ in perturbation theory. The subtraction in the first term is performed for each momentum and then the sum over momenta is performed (see below).

## The procedure

11 The result for the width is expressed in terms of $G_{F}$, the Fermi constant $\left(G_{F}=1.16632(2) \times 10^{-5} \mathrm{GeV}^{-2}\right)$. This is obtained from the muon lifetime:

$$
\frac{1}{\tau_{\mu}}=\frac{G_{F}^{2} m_{\mu}^{5}}{192 \pi^{3}}\left[1-\frac{8 m_{e}^{2}}{m_{\mu}^{2}}\right]\left[1+\frac{\alpha}{2 \pi}\left(\frac{25}{4}-\pi^{2}\right)\right]
$$

S.M.Berman, PR 112 (1958) 267; T.Kinoshita and A.Sirlin, PR 113 (1959) 1652

- This expression can be viewed as the definition of $G_{F}$. Many EW corrections are absorbed into the definition of $G_{F}$; the explicit $O(\alpha)$ corrections come from the following diagrams in the effective theory:

together with the diagrams with a real photon.
- The diagrams are evaluated in the $W$-regularisation in which the photon propagator is modified by:
A.Sirlin, PRD 22 (1980) 971

$$
\frac{1}{k^{2}} \rightarrow \frac{M_{W}^{2}}{M_{W}^{2}-k^{2}} \frac{1}{k^{2}}
$$

$$
\left(\frac{1}{k^{2}}=\frac{1}{k^{2}-M_{W}^{2}}+\frac{M_{W}^{2}}{M_{W}^{2}-k^{2}} \frac{1}{k^{2}}\right)
$$

## The procedure (cont.)

2. Most (but not all) of the EW corrections which are absorbed in $G_{F}$ are common to other processes (including pion decay) $\Rightarrow$ factor in the amplitude of

$$
\left(1+3 \alpha / 4 \pi(1+2 \bar{Q}) \log M_{Z} / M_{W}\right), \text { where } \bar{Q}=\frac{1}{2}\left(Q_{u}+Q_{d}\right)=1 / 6
$$

A.Sirlin, NP B196 (1982) 83; E.Braaten \& C.S.Li, PRD 42 (1990) 3888

3 We therefore need to calculate the pion-decay diagrams in the effective theory (with $\left.H_{\text {eff }} \propto\left(\bar{d}_{L} \gamma^{\mu} u_{L}\right)\left(\bar{v}_{\ell, L} \gamma_{\mu} \ell_{L}\right)\right)$ in the $W$-regularization. These can be related to the lattice theory by perturbation theory, e.g. for Wilson fermions:

$$
O_{L L}^{W-\mathrm{reg}}=\left(1+\frac{\alpha}{4 \pi}\left(2 \log a^{2} M_{W}^{2}-15.539\right)+O\left(\alpha \alpha_{s}\right)\right) O_{L L}^{\mathrm{bare}}
$$

4 We now return to the master formula:

$$
\Gamma_{0}+\Gamma_{1}(\Delta)=\lim _{V \rightarrow \infty}\left(\Gamma_{0}-\Gamma_{0}^{\mathrm{pt}}\right)+\lim _{V \rightarrow \infty}\left(\Gamma_{0}^{\mathrm{pt}}+\Gamma_{1}(\Delta)\right) .
$$

- The term which is added and subtracted is not unique, but we require that both terms are free of ir divergences and independent of the ir regulator.
- Kinoshita performed the calculation for a pointlike pion, (i) integrating over all phase space and (ii) imposing a cut-off on the charged-lepton energy.
T.Kinoshita, PRL 2 (1959) 477
- We have reproduced these results and extended them to a cut-off on the photon energy.

## The procedure (Cont)

[5 Consider now the evaluation of the first term in the master formula.

(a)

(b)

(c)

- The correlation function for this set of diagrams is of the form:

$$
C_{1}(t)=\frac{1}{2} \int d^{3} \vec{x} d^{4} x_{1} d^{4} x_{2}\langle 0| T\left\{J_{W}^{v}(0) j^{\mu}\left(x_{1}\right) j_{\mu}\left(x_{2}\right) \phi^{\dagger}(\vec{x}, t)\right\}|0\rangle \Delta\left(x_{1}, x_{2}\right)
$$

where $j_{\mu}(x)=\sum_{f} Q_{f} \bar{f}(x) \gamma_{\mu} f(x), J_{W}$ is the weak current, $\phi$ is an interpolating operator for the pion and $\Delta$ is the photon propagator.

- Combining $C_{1}$ with the lowest order correlator:

$$
C_{0}(t)+C_{1}(t) \simeq \frac{e^{-m_{\pi} t}}{2 m_{\pi}} Z^{\phi}\langle 0| J_{W}^{v}(0)\left|\pi^{+}\right\rangle
$$

where now $O(\alpha)$ terms are included.

- $e^{-m_{\pi} t} \simeq e^{-m_{\pi}^{0} t}\left(1-\delta m_{\pi} t\right)$ and $Z^{\phi}$ is obtained from the two-point function.

## The procedure (cont.)

- Diagrams (e) and (f) are not simply generalisations of the evaluation of $f_{\pi}$. The leptonic part is treated using perturbative propagators.
(There are also disconnected diagrams to be evaluated.)
- We have to be able to isolate the finite-volume ground state (pion).
- The Minkowski $\leftrightarrow$ Euclidean continuation can be performed (the time integrations are convergent).
- Finite volume effects, expected to be $O\left(1 /\left(L \Lambda_{\mathrm{QCD}}\right)^{n}\right)$, being investigated.
- The next step will be to start implementing this procedure.
- As we learn how to do such calculations it will be useful to consider simpler quantities such as $\Gamma\left(\pi \rightarrow \mu v_{\mu}(\gamma)\right) / \Gamma\left(\pi \rightarrow e v_{e}(\gamma)\right)$.
- We warmly thank Norman, Bob and Peter, the LOC and all their colleagues at Columbia and Brookhaven who have helped to make Lattice 2014 such a stimulating, enjoyable and beautifully organised conference.

Photos courtesy of H.Wittig.

- In this talk I have described the current status of three projects involving long-distance effects:
$11 \Delta m_{K}=m_{K_{L}}-m_{K_{s}}$.
12 Rare kaon decays.
3 Electromagnetic corrections to leptonic decays.
- The early results and indications are very promising indeed, but much more work needs to be done.
- As an example consider the behaviour of the integrated $Q_{1}-Q_{1}$ correlation function without GIM subtraction but with an artificial cut-off, $R=\sqrt{ }\left\{\left(t_{2}-t_{1}\right)^{2}+\left(\vec{x}_{2}-\vec{x}_{1}\right)^{2}\right\}$ on the coordinates of the two $Q_{1}$ insertions.

N.Christ, T.Izubuchi, CTS, A.Soni \& J.Yu, arXiv:1212.5931
- The plot exhibits the quadratic divergence as the two operators come together.
- The quadratic divergence is cancelled by the GIM mechanism.
