# A simple system with I = 0 and $J^{PC} = 0^{++}$ .

• Our principal state of interest is the  $\sigma$  or  $f_0(500)$  due to its mysterious nature and debated partonic content. For the unphysical  $2m_{\pi} > m_{\sigma}$ , we can measure the mass of the  $\sigma$  directly.

$$C(t) = \sum_{\vec{\rho}} A_{\vec{\rho}} e^{-E_{2\pi(\vec{\rho})}t} + B e^{-m_{\sigma}t} + \dots$$

In the  $2m_{\pi} < m_{\sigma}$  regime, we will use Lüscher's approach of obtaining the scattering phase shift  $\delta(s)$  in the two-pion, flavour singlet channel.

ヘロン 人間 とくほ とくほ とう

# A simple system with I = 0 and $J^{PC} = 0^{++}$ .

The Correlation Function

$$C(t) = \sum_{\vec{x}, \vec{y}, \vec{z}} \langle 0 | T\{ P_{-}(t, \vec{z}) P_{+}(t, \vec{y}) P_{+}(0, \vec{x}) P_{-}(0, \vec{0}) \} | 0 \rangle$$

Let:

$$P_{-}(t,\vec{z}), P_{+}(t,\vec{y}) \rightarrow \bar{d}(z)\gamma_{5}u(z), \bar{u}(y)\gamma_{5}d(y)$$
$$P_{-}(0,\vec{x}), P_{+}(0,\vec{0}) \rightarrow \bar{d}(x)\gamma_{5}u(x), \bar{u}(0)\gamma_{5}d(0)$$

and perform all possible Wick contractions on the quark operators.

・ロ・ ・ 同・ ・ ヨ・ ・ ヨ・

# **Quark Propagator Diagrams**

One would place a point source at 0 and one at Z and use  $\gamma_5$  conjugation to calculate  $C_{sum}(t)$ .

★ E > < E >

э

# Quark Propagator Diagrams

 $C_2(t)$  and  $C_3(t)$  are hermitian conjugate. This will save some calculation time, but not very much compared to inversions.

★ Ξ → ★ Ξ →

< 🗇 🕨

## **Disconnected Parts.**

• We can remove the disconnected parts when calculating the correlation function values to leave the purely connected contribution.

$$C_{0}(t) \neq \sum_{\vec{x}, \vec{y}, \vec{z}} \langle \operatorname{Tr}[S(y, 0)S^{\dagger}(y, 0)] \rangle \langle \operatorname{Tr}[S(z, x)S^{\dagger}(z, x)] \rangle_{U}$$
  
$$= \sum_{\vec{x}, \vec{y}, \vec{z}} \left[ \langle \operatorname{Tr}[S(y, 0)S^{\dagger}(y, 0)] - \langle \operatorname{Tr}[S(y, 0)S^{\dagger}(y, 0)] \rangle_{U} \rangle_{U} \right] \rangle_{U} \langle \operatorname{Tr}[S(z, x)S^{\dagger}(z, x)] - \langle \operatorname{Tr}[S(z, x)S^{\dagger}(z, x)] \rangle_{U} \rangle_{U} \rangle_{U}$$

This will tend to reduce the absolute value of correlation functions and errors will become much more significant. This procedure is repeated for  $C_1(t)$ .

#### QCD Setup Stochastic Sources Error Analysis on Z<sub>2</sub>

# QCD Setup

We performed a quenched calculation using a clover improved operator on a  $4^{3}8$  lattice with periodic B.C. and the following:

Param.	Beta	m₀a	$am_{\pi}$	a(GeV <sup>-1</sup> )	$m_{\pi}(\text{GeV})$	Therm	Skip	Config.
Value	5.96	-0.3	1.0	0.51	2.0	5000	200	100

High Beta places the system well into the deconfinement (high-temperature) phase with very unphysical pion masses. However, some studies have shown that when  $m_{\sigma} < m_{2\pi}$ , one may treat the  $\sigma$  as a bound state. <sup>12</sup> In this regime,  $m_{\sigma}$  is the lowest energy state.

QCD Setup Stochastic Sources Error Analysis on Z<sub>2</sub>

# **Stochastic Sources**

 Point sources are resource intensive. One must perform
 N<sub>col</sub> × N<sub>spin</sub> × L<sup>3</sup>T inversions per data point for
 spin-colour-time dilution.

$$M_{ab}|\phi_b
angle = \left(egin{array}{c} 1\ 0\ dots\ 0\ \end{pmatrix}$$

 Stochastic sources can significantly reduce the number of required inversions for moderate to large lattice sizes.

イロト 不得 とくほと くほとう

QCD Setup Stochastic Sources Error Analysis on Z<sub>2</sub>

# **Stochastic Sources**

Consider some set of vectors  $|\eta_b^i\rangle$  such that:

$$\lim_{\substack{N_R \to \infty}} \frac{1}{N_R} \sum_{i=1}^{N_R} |\eta_b^i \rangle \langle \eta_c^i| = \delta_{bc}$$
$$\lim_{\substack{N_R \to \infty}} \frac{1}{N_R} \sum_{i=1}^{N_R} |\eta_b^i \rangle = 0$$

We can take advantage of this by inverting  $M_{ab}|\phi_b\rangle = |\eta_a^i\rangle N_R$  times for some  $N_R$  number of vectors:

$$\Rightarrow \lim_{N_R \to \infty} \frac{1}{N_R} \sum_{i=1}^{N_R} M_{ab} |\phi_b\rangle \langle \eta_c^i | = \delta_{ac}$$

...but how big does  $N_R$  have to be in order to get a trustworthy approximation to the true propagator?

QCD Setup Stochastic Sources Error Analysis on Z<sub>2</sub>

# M.S.E, Variance, and Bias

• To answer this question, we chose to investigate the Mean Square Error, Variance, and Bias of the purely stochastic contribution to the error budget for *Z*<sub>2</sub>.

$$M.S.E.[X_{sto}] = Var[X_{sto}] + Bias^{2}[X_{sto}],$$

$$M.S.E.[X_{sto}] = rac{1}{n} \sum_{i=1}^{n} [X_{sto} - X_{ps}]^2$$
  
 $Bias[X_{sto}] = rac{1}{n} \sum_{i=1}^{n} [X_{sto} - X_{ps}].$ 

ヘロト 人間 とくほとくほとう

QCD Setup Stochastic Sources Error Analysis on Z<sub>2</sub>

# M.S.E, Variance, and Bias

 To answer this question, we chose to investigate the Mean Square Error, Variance, and Bias of the purely stochastic contribution to the error budget for Z<sub>2</sub> and Gaussian sources.

$$M.S.E.\left[\frac{X_{sto}(t)}{X_{ps}(t)}\right] = Var\left[\frac{X_{sto}(t)}{X_{ps}(t)}\right] + Bias^{2}\left[\frac{X_{sto}(t)}{X_{ps}(t)}\right],$$

$$M.S.E.\left[\frac{X_{sto}(t)}{X_{ps}(t)}\right] = \frac{1}{n} \sum_{i=1}^{n} \left[\frac{X_{sto}(t)}{X_{ps}(t)} - 1\right]^{2}$$
$$Bias\left[\frac{X_{sto}(t)}{X_{ps}(t)}\right] = \frac{1}{n} \sum_{i=1}^{n} \left[\frac{X_{sto}(t)}{X_{ps}(t)} - 1\right].$$

イロト 不得 とくほ とくほとう

æ

QCD Setup Stochastic Sources Error Analysis on Z<sub>2</sub>

# **Bias Rather Than Variance**

Bias is the main source of error:

$$\begin{split} S_{true}^{-1} &= S_{ab}^{-1} \approx \sum M_{ab}^{-1} |\eta_b\rangle \langle \eta_c | \\ \mathrm{Tr}[S_{ab}^{-1}S_{ab}^{-1\dagger}] \approx \sum M_{ab}^{-1} \underbrace{|\eta_b\rangle \langle \eta_c |\eta_c\rangle \langle \eta_d|}_{\mathrm{Off}\text{-diags} > 0} M_{ad}^{-1\dagger} \\ \\ \mathrm{Solution} \to \mathrm{Tr}[S_{ab}^{-1}S_{ab}^{-1\dagger}] \approx \sum M_{ab}^{-1} \underbrace{|\eta_b\rangle \langle \eta_c |\xi_c\rangle \langle \xi_d|}_{\mathrm{Off}\text{-diags} \approx 0 \pm \epsilon} M_{ad}^{-1\dagger} \end{split}$$

N.B. This is why  $Z_2$  out-performs other distributions. Off-diagonal terms contribute roughly the same error<sup>3</sup> for any parent distribution, but the unit size and bimodality of  $Z_2$  *enforces* the leading diagonal to be the identity.

Software and Hardware Benchmarks

# Software

We use the functionality of CPS and replaced its inversion function with one from QUDA. This required us to:

- Rearrange the clover matrix
- Rearrange the gauge field SU(3) matrices
- Write GPU kernels for the matrix algebra

One simply replaces the CPS file: src/util/lattice/f\_clover/f\_clover.C

QUDA need not be modified. Instructions can be found at www.rpi.edu/~giedtj/

Software and Hardware Benchmarks

# Summary

- Scalar States can be investigated in the *I* = 0 flavour singlet channel using π<sub>+</sub>π<sub>-</sub> → π<sub>+</sub>π<sub>-</sub>.
- Stochastic Sources are a viable option to significanly reduce calculation time with acceptable error, if used judiciously.
- GPU Architecture is a cheap, under utilised resource, waiting to be exploited.
- Outlook
  - Other statistical techniques such as Gaussian/Stout Smearing can be investigated.
  - Using Momentum sources could make inversion time insignificant, but one must fix to Landau gauge.
  - As soon as resources are secured, we can perform the calculations on Larger Lattices and extract physics.
