Sign Problem Solution

Review: Staggered Fermions

• Discretized version of the Dirac Hamiltonian that introduces a single fermion field component to each lattice site and interprets doubling as physical flavors.

Review: Staggered Fermions

- Discretized version of the Dirac Hamiltonian that introduces a single fermion field component to each lattice site and interprets doubling as physical flavors.
- In two dimensions, given by

$$H = t \sum_{x} \left[\frac{i}{2} \left(c_x^{\dagger} c_{x+\hat{\alpha}_1} - c_x^{\dagger} c_{x-\hat{\alpha}_1} \right) + \frac{i}{2} (-1)^{x_1} \left(c_x^{\dagger} c_{x+\hat{\alpha}_2} - c_x^{\dagger} c_{x-\hat{\alpha}_2} \right) \right]$$
(1)

Review: Staggered Fermions

- Discretized version of the Dirac Hamiltonian that introduces a single fermion field component to each lattice site and interprets doubling as physical flavors.
- In two dimensions, given by

$$H = t \sum_{x} \left[\frac{i}{2} \left(c_x^{\dagger} c_{x+\hat{\alpha}_1} - c_x^{\dagger} c_{x-\hat{\alpha}_1} \right) + \frac{i}{2} (-1)^{x_1} \left(c_x^{\dagger} c_{x+\hat{\alpha}_2} - c_x^{\dagger} c_{x-\hat{\alpha}_2} \right) \right]$$
(1)

Can be written as

$$H = t \sum_{xy} c_x^{\dagger} M_{xy} c_y, \qquad (2)$$

where

$$M_{xy} = \frac{i}{2} \left(\delta_{x + \hat{\alpha}_{1}, y} - \delta_{x - \hat{\alpha}_{1}, y} \right) + \frac{i}{2} \left(-1 \right)^{x_{1}} \left(\delta_{x + \hat{\alpha}_{2}, y} - \delta_{x - \hat{\alpha}_{2}, y} \right).$$
(3)

Review: Staggered Fermions

- Discretized version of the Dirac Hamiltonian that introduces a single fermion field component to each lattice site and interprets doubling as physical flavors.
- In two dimensions, given by

$$H = t \sum_{x} \left[\frac{i}{2} \left(c_x^{\dagger} c_{x+\hat{\alpha}_1} - c_x^{\dagger} c_{x-\hat{\alpha}_1} \right) + \frac{i}{2} (-1)^{x_1} \left(c_x^{\dagger} c_{x+\hat{\alpha}_2} - c_x^{\dagger} c_{x-\hat{\alpha}_2} \right) \right]$$
(1)

Can be written as

$$H = t \sum_{xy} c_x^{\dagger} M_{xy} c_y, \qquad (2)$$

where

$$M_{xy} = \frac{i}{2} \left(\delta_{x + \hat{\alpha}_{1}, y} - \delta_{x - \hat{\alpha}_{1}, y} \right) + \frac{i}{2} \left(-1 \right)^{x_{1}} \left(\delta_{x + \hat{\alpha}_{2}, y} - \delta_{x - \hat{\alpha}_{2}, y} \right).$$
(3)

• Particle-hole symmetry: $c_x \rightarrow \sigma_x c_x^{\dagger}$, $\sigma_x = (-1)^{x_1+x_2}$

No doubling in time dimension. The four zero modes at the corners of the 2d Brillouin zone can be interpreted as N_f = 1 (4-component) Dirac fermion.

Motivation to use Hamiltonian Formalism

- No doubling in time dimension. The four zero modes at the corners of the 2d Brillouin zone can be interpreted as $N_f = 1$ (4-component) Dirac fermion.
- We may then add in a second flavor, and get an SU(2) flavor symmetry.

- No doubling in time dimension. The four zero modes at the corners of the 2d Brillouin zone can be interpreted as N_f = 1 (4-component) Dirac fermion.
- We may then add in a second flavor, and get an SU(2) flavor symmetry.
- For Lagrangian approach, there would be doubling by a factor of 8 due to time dimension. We would naturally get $N_f = 2$ Dirac fermions, and there would be no SU(2) flavor symmetry.

- No doubling in time dimension. The four zero modes at the corners of the 2d Brillouin zone can be interpreted as N_f = 1 (4-component) Dirac fermion.
- We may then add in a second flavor, and get an SU(2) flavor symmetry.
- For Lagrangian approach, there would be doubling by a factor of 8 due to time dimension. We would naturally get $N_f = 2$ Dirac fermions, and there would be no SU(2) flavor symmetry.
- There's an issue with Hamiltonian fermions though: sign problems in some models.

- No doubling in time dimension. The four zero modes at the corners of the 2d Brillouin zone can be interpreted as N_f = 1 (4-component) Dirac fermion.
- We may then add in a second flavor, and get an SU(2) flavor symmetry.
- For Lagrangian approach, there would be doubling by a factor of 8 due to time dimension. We would naturally get $N_f = 2$ Dirac fermions, and there would be no SU(2) flavor symmetry.
- There's an issue with Hamiltonian fermions though: sign problems in some models.
- The solution? Fermion bag approach.

$$= \int [d\phi] e^{-S[\phi]} \det M(\phi) \tag{7}$$

 We have a sum of determinants. In some models this method will still work if we can find a "pairing mechanism." Example: Even numbers of flavors can lead to squares of the determinant. But odd numbers of flavors (such as this model) typically lead to sign problems.

- We have a sum of determinants. In some models this method will still work if we can find a "pairing mechanism." Example: Even numbers of flavors can lead to squares of the determinant. But odd numbers of flavors (such as this model) typically lead to sign problems.
- Another problem: particle hole symmetry is lost in the naive method.

- This trace can be evaluated exactly in terms of the determinant of a 2k × 2k matrix, G([b, s, t]).
- Thus we have:

$$Z = Z_0 \sum_{k} \sum_{[b,s]} \int [dt] \left(-\frac{V}{4} \right)^k \det G([b, s, t])$$
(14)
$$G = \begin{pmatrix} d_{11}[s] & a_{12} & \vdots & a_{13} & a_{14} \\ -a_{12} & d_{22}[s] & \vdots & a_{23} & a_{24} \\ \dots & \dots & \dots & \dots \\ a_{13} & a_{23} & \vdots & d_{33}[s] & a_{34} \\ a_{14} & a_{24} & \vdots & -a_{34} & d_{44}[s] \end{pmatrix}$$
(15)

• The following identities hold: $a_{yx} = -\sigma_x a_{xy} \sigma_y$ and $d_{xx}[s] = -\frac{s_x}{2}$.

The Sign Problem

• However, no guarantee that these determinants will be positive. Under particle-hole symmetry, $[s] \rightarrow [-s]$, so not symmetric for fixed *s*.

The Sign Problem

- However, no guarantee that these determinants will be positive. Under particle-hole symmetry, $[s] \rightarrow [-s]$, so not symmetric for fixed *s*.
- In fact, in generating 10,000 such determinants randomly, we find a severe sign problem:

The Sign Problem

- However, no guarantee that these determinants will be positive. Under particle-hole symmetry, $[s] \rightarrow [-s]$, so not symmetric for fixed *s*.
- In fact, in generating 10,000 such determinants randomly, we find a severe sign problem:

Figure: 10,000 determinants: 5004 were positive and 4996 were negative.

 In our model each diagonal element can be treated as a fermion bag dependent on [s]. Since dependence on auxiliary bosonic field [s] is freely fluctuating, we can integrate it out.

- In our model each diagonal element can be treated as a fermion bag dependent on [s]. Since dependence on auxiliary bosonic field [s] is freely fluctuating, we can integrate it out.
- Thus, consider the [s] sum:

$$\sum_{[s]} Det(G[b, s, t])$$
(16)

- In our model each diagonal element can be treated as a fermion bag dependent on [s]. Since dependence on auxiliary bosonic field [s] is freely fluctuating, we can integrate it out.
- Thus, consider the [s] sum:

$$\sum_{[s]} Det(G[b, s, t])$$
(16)

• We may write this determinant in Grassman integral form:

$$\sum_{[s]} \int \left[d\bar{\psi} d\psi \right] e^{-\bar{\psi}((D_0[s]) + \mathcal{A}([b,t]))\psi}$$
(17)

- In our model each diagonal element can be treated as a fermion bag dependent on [s]. Since dependence on auxiliary bosonic field [s] is freely fluctuating, we can integrate it out.
- Thus, consider the [s] sum:

$$\sum_{[s]} Det(G[b, s, t])$$
(16)

• We may write this determinant in Grassman integral form:

$$\sum_{[s]} \int \left[d\bar{\psi} d\psi \right] e^{-\bar{\psi}((D_0[s]) + \mathcal{A}([b,t]))\psi}$$
(17)

• We first sum up the diagonal portion.

The Diagonal Sum

• We note that for the diagonal part:

$$\sum_{[s]} e^{-\bar{\psi}D_0([s])\psi} = \prod_q \sum_{s_q=1,-1} \left(1 + \frac{s_q}{2}\bar{\psi}_q\psi_q\right)$$
(18)

크

イロト イヨト イヨト イヨ

The Diagonal Sum

• We note that for the diagonal part:

$$\sum_{[s]} e^{-\bar{\psi}D_0([s])\psi} = \prod_q \sum_{s_q=1,-1} \left(1 + \frac{s_q}{2}\bar{\psi}_q\psi_q\right)$$
(18)

• Which is simply:

$$\prod_{q} 2 = 4^k \tag{19}$$

The Diagonal Sum

• We note that for the diagonal part:

$$\sum_{[s]} e^{-\bar{\psi}D_0([s])\psi} = \prod_q \sum_{s_q=1,-1} \left(1 + \frac{s_q}{2}\bar{\psi}_q\psi_q\right)$$
(18)

• Which is simply:

$$\prod_{q} 2 = 4^k \tag{19}$$

< □ > < □ > < □ > < □ >

• Thus our partition function is now given by:

$$Z = \sum_{[b]} \int [dt] (-V)^k Det (A([b, t]))$$
(20)

 Alternatively, we can see how this works using the pictorial representation of determinants. For example, a 2 × 2 determinant can be represented as:

 Alternatively, we can see how this works using the pictorial representation of determinants. For example, a 2 × 2 determinant can be represented as:

$$1 \bigcirc 2 \bigcirc + 1 \bigcirc 2$$

< ロ > < 同 > < 回 > < 回 >

 Alternatively, we can see how this works using the pictorial representation of determinants. For example, a 2 × 2 determinant can be represented as:

$$1 \bigcirc 2 \bigcirc + 1 \bigcirc 2$$

• In our sum of the $D_0 + A$ determinants, for every term of the form

$$\bigcirc \qquad \bigcirc \qquad \cdots \qquad \stackrel{i \bigcirc}{\underset{s_t=1}{\bigcirc}} \qquad \cdots \qquad \bigcirc$$

・ロト ・ 同ト ・ ヨト ・ ヨ

 Alternatively, we can see how this works using the pictorial representation of determinants. For example, a 2 × 2 determinant can be represented as:

$$1 \bigcirc 2 \bigcirc + 1 \bigcirc 2$$

• In our sum of the $D_0 + A$ determinants, for every term of the form

$$\bigoplus_{s_t=1} \cdots \bigoplus_{s_t=1} \cdots \bigoplus_{$$

We have one with the form

 Alternatively, we can see how this works using the pictorial representation of determinants. For example, a 2 × 2 determinant can be represented as:

• In our sum of the $D_0 + A$ determinants, for every term of the form

$$\bigoplus_{s_t=1} \cdots \bigoplus_{s_t=1} \cdots \bigoplus_{$$

We have one with the form

$$\bigoplus_{s_i=-1} \cdots \bigoplus_{s_i=-1} \cdots \bigoplus_{s_i=-1} \cdots$$

• A([t]) satisfies the relation $A^{T} = -\tilde{D}A\tilde{D}, (\tilde{D}_{xy} = \sigma_{x}\delta_{xy})$ so:

$$\left(A\tilde{D}\right)^{T}=-A\tilde{D}$$
 (21)

A D M A A A M M

• A([t]) satisfies the relation $A^{T} = -\tilde{D}A\tilde{D}, (\tilde{D}_{xy} = \sigma_{x}\delta_{xy})$ so:

$$\left(A\tilde{D}\right)^{T}=-A\tilde{D}$$
 (21)

But Det (D
 is (-1)^k, since there are k even sites and k odd sites. Thus:

$$(-1)^{k} \operatorname{Det} \left(A([b,t]) \right) = \operatorname{Det} \left(A \tilde{D} \right) \geq 0$$
(22)

• A([t]) satisfies the relation $A^{T} = -\tilde{D}A\tilde{D}, (\tilde{D}_{xy} = \sigma_{x}\delta_{xy})$ so:

$$\left(A\tilde{D}\right)^{T} = -A\tilde{D}$$
 (21)

But Det (D
 is (-1)^k, since there are k even sites and k odd sites. Thus:

$$(-1)^{k} \operatorname{Det} \left(A([b,t]) \right) = \operatorname{Det} \left(A \tilde{D} \right) \geq 0$$
(22)

And we have:

$$Z = \sum_{[b]} \int [dt] (V)^k \operatorname{Det} \left(A([b, t]) \tilde{D} \right)$$
(23)

• A([t]) satisfies the relation $A^{T} = -\tilde{D}A\tilde{D}, (\tilde{D}_{xy} = \sigma_{x}\delta_{xy})$ so:

$$\left(A\tilde{D}\right)^{T} = -A\tilde{D}$$
 (21)

But Det (D
 is (-1)^k, since there are k even sites and k odd sites. Thus:

$$(-1)^{k} \operatorname{Det} \left(A([b,t]) \right) = \operatorname{Det} \left(A \tilde{D} \right) \geq 0$$
(22)

And we have:

$$Z = \sum_{[b]} \int [dt] (V)^k \operatorname{Det} \left(A([b, t]) \tilde{D} \right)$$
(23)

• We have solved the sign problem. (For repulsive model!)

Some Example Determinants

 100 such determinants, randomly selected. All were confirmed to be positive.

Some Example Determinants

- 100 such determinants, randomly selected. All were confirmed to be positive.
- Note that the probability of positive weight configurations is exponentially smaller, because the -logdet value is larger.

• Even with particle-hole symmetry, some models still have sign problems. However, we have solved a class of them.

- Even with particle-hole symmetry, some models still have sign problems. However, we have solved a class of them.
- Thus we have new solutions to sign problems applicable to Hamiltonian lattice fermions. Can solve four-fermion models with staggered fermions.

- Even with particle-hole symmetry, some models still have sign problems. However, we have solved a class of them.
- Thus we have new solutions to sign problems applicable to Hamiltonian lattice fermions. Can solve four-fermion models with staggered fermions.
- We've shown this works for staggered fermions, but other models can be solved with it, such as models with an odd number of flavors: SU(3) Gross-Neveu models.

- Even with particle-hole symmetry, some models still have sign problems. However, we have solved a class of them.
- Thus we have new solutions to sign problems applicable to Hamiltonian lattice fermions. Can solve four-fermion models with staggered fermions.
- We've shown this works for staggered fermions, but other models can be solved with it, such as models with an odd number of flavors: SU(3) Gross-Neveu models.
- Or we can add a staggered mass term that puts particles on the even sublattice and holes on the odd sublattice.

- Even with particle-hole symmetry, some models still have sign problems. However, we have solved a class of them.
- Thus we have new solutions to sign problems applicable to Hamiltonian lattice fermions. Can solve four-fermion models with staggered fermions.
- We've shown this works for staggered fermions, but other models can be solved with it, such as models with an odd number of flavors: SU(3) Gross-Neveu models.
- Or we can add a staggered mass term that puts particles on the even sublattice and holes on the odd sublattice.
- Possible to study new quantum critical behavior.
